$$J_2 = J_0 \pm m_2 \quad \text{and} \quad f_2 = f_0 \pm l_2 \qquad [37]$$

When Equation [36] is written in terms of nondimensional parameters, the expression is

$$\epsilon(t) = \frac{\sigma_2p + 2\alpha_2\zeta_2\omega_{n2}}{p^2 + 2\zeta_2\omega_{n2}p + \omega_{n2}{}^2}\,\omega_i(t) \qquad [38]$$

where

$$\left.\begin{aligned} \sigma_2 &= \frac{J_0}{J_2}, & \zeta_2 &= \frac{f_2}{2\sqrt{J_2k_2}} \\ \alpha_2 &= \frac{f_0}{f_2}, & \omega_{n2} &= \sqrt{\frac{k_2}{J_2}} \end{aligned}\right\} \qquad [39]$$

The general form of the roots of the denominator of Equation [38] are

$$r_1, r_2 = -\zeta_2\omega_{n2} \pm j\omega_{n2}\sqrt{1-\zeta_2{}^2} = \frac{1}{\tau_2} \pm j\omega_2 \qquad [40]$$

The solution of Equation [38] in dimensionless form for the case of a velocity ω_i suddenly applied to the input member with the system at rest, with ω_i afterward maintained constant, and with ζ_2 less than unity is

$$\frac{\epsilon(t)}{\epsilon_{ss}} = \left[1 - e^{-\frac{t}{\tau_2}}\left(\cos\frac{\sqrt{1-\zeta_2{}^2}}{\zeta_2}\frac{t}{\tau_2} + \frac{2\alpha_2\zeta_2{}^2 - 1}{2\alpha_2\zeta_2\sqrt{1-\zeta_2{}^2}}\sin\frac{\sqrt{1-\zeta_2{}^2}}{\zeta_2}\frac{t}{\tau_2}\right)\right] \qquad [41]$$

With critical damping the solution is

$$\frac{\epsilon(t)}{\epsilon_{ss}} = 1 - e^{-\frac{t}{\tau_2}}\left(1 + \frac{t}{\tau_2}\right) + \frac{1}{2\alpha_2}\frac{t}{\tau_2}e^{-\frac{t}{\tau_2}} \qquad [42]$$

where in each instance

$$\epsilon_{ss} = \frac{2\alpha_2\zeta_2}{\omega_{n2}}\,\omega_i \qquad [43]$$

Equations [41] and [42] therefore indicate the transient response of a servomechanism with a type 2 controller when subjected to a velocity disturbance.

When obtaining the transient response of a servomechanism with a controller which has derivative response, it should be remembered that $p^2\theta_i$ is an infinite impulse at $t = 0$ when a velocity ω_i is suddenly applied, and that both $p\theta_i$ and $p^2\theta_i$ are infinite impulses at $t = 0$ when an angle is suddenly applied. If the law of control given by Equation [34] is assumed to hold at all times, and these particular test disturbances are applied, the controller is required to deliver an infinite torque for zero time at $t = 0$. This, of course, is a requirement that no physical controller can fulfill. Thus a word of warning is appropriate here concerning the matter of using the methods of Heaviside's operational calculus (2, 9) to obtain the solution of expressions of the form of Equation [38] for an applied step function of velocity or angle. Operational calculus methods as ordinarily applied will assume the controller to be ideal and to comply with the law of control at all times. Solutions performed using the methods of LaPlace (9, 22) will introduce the boundary conditions applicable to the particular system conditions. The results given herein for the transient response of servos using derivative control recognize (*a*) that the maximum torque of the controller is limited and (*b*) that a finite torque applied to a mass member for zero time causes no change in its velocity or angle. The solution given by Equations [40] and [41] are derived on the basis that at a time immediately following the application of a suddenly applied velocity, that is, at $t = 0^+$

$$\left.\begin{aligned} &\epsilon, \theta_i, \text{ and } \theta_0 = \text{zero};\ p\epsilon = p\theta_i = \omega_i \\ &p\theta_0 = \text{zero};\ p^2\theta_i = \text{zero} \\ &p^2\epsilon = -p^2\theta_0 \end{aligned}\right\} \qquad [44]$$

An examination of Equations [36], [41], and [42] indicates certain points regarding the algebraic sign which should be used with the coefficients l_2 and m_2 of Equation [34] to give the best system performance. For example, since the coefficient f_2 in Equation [36] must be positive to insure stability, and since the principal argument for derivative control is to allow output damping to be negligible, only the use of the positive algebraic sign with the coefficient l_2 has practical significance.

For design purposes quantitative data concerning the effects of varying the magnitude of first-derivative response in the controller are highly desirable. If it is assumed, in the interests of simplicity, that the entire damping is supplied by l_2, (the so-called derivative damping) α_2 is zero and the steady-state error as given by Equation [43] is zero. Equations [41] and [42] for the transient response can then be written in a form convenient for the study of the effects of varying l_2 as

$$\frac{\epsilon(t)\omega_{n2}}{\omega_i} = \frac{1}{\sqrt{1-\zeta_2^2}} e^{-\zeta_2\omega_{n2}t} \sin\sqrt{1-\zeta_2^2}\,\omega_{n2}t \Bigg|_{\alpha_2=0} \quad \ldots [41a]$$

for the oscillatory case, and as

$$\frac{\epsilon(t)\omega_{n2}}{\omega_i} = \omega_{n2}t\, e^{-\omega_{n2}t} \Bigg|_{\alpha_2=0} \quad \ldots\ldots\ldots\ldots [42a]$$

for the critically damped case.

The nature of the transient response of the system now obtained is well illustrated by the family of curves in Fig. 6 which shows the plot of $\frac{\epsilon(t)\omega_{n2}}{\omega_i}$ as a function of the dimensionless quantity $\omega_{n2}t$ for various values of ζ_2. To the extent that angle is considered dimensionless the curves in Fig. 6 are dimensionless. Load torque and coulomb friction are assumed zero in addition to output damping being zero. Since the abscissa variable ω_{n2} is not affected by changes in l_2 this family of curves indicates directly the true relative times of duration of the transient for the values of ζ_2 assumed. The curves also show some rather interesting conditions. For example, the error is substantially independent of ζ_2 when $\omega_{n2}t$ is approximately 3. Also any benefits which might result from attempting to decrease the time of the duration of the transient by decreasing ζ_2 are offset to some extent by an increase in the peak magnitude of the transient error. Specifically, a decrease in ζ_2 from unity to 0.8 decreases the time of the duration of the transient by about 30 per cent, but increases the peak error during the transient by about 13 per cent. Since a decrease in ζ_2 tends to decrease the controller design difficulties and costs, there appears therefore to be genuine merit in the use of a type 2 controller adjusted to give values of ζ_2 such that $0.6 < \zeta_2 < 1.0$, unless a system that oscillates even to only a slight extent is barred because of circumstances peculiar to the particular application.

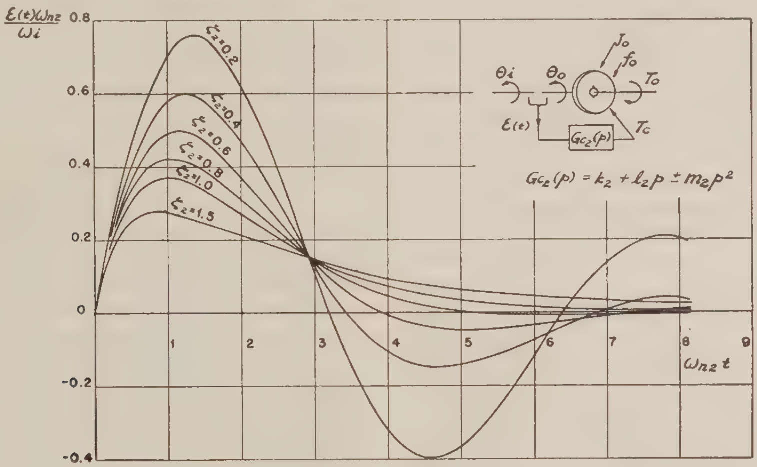

Fig. 6 Transient Error Curves for a Servomechanism With a Type 2 Controller With $\alpha_2 = 0$ and With σ_2 Constant, When Subjected to a Suddenly Applied Input Velocity ω_i

The task of making available a controller that will establish the component of first-derivative response with a high degree of fidelity is frequently somewhat difficult. When it comes to making available a controller that will establish a component of second-derivative response the task becomes one of another order of difficulty. Even the problem of providing a component of response that merely resembles second derivative is frequently difficult. It is highly desirable therefore that a designer have available quantitative data to aid him in balancing the cost of producing a certain amount of second-derivative response against the improvement in the performance of the system which the use of this amount affords.

This matter concerns the question of both the algebraic sign and the magnitude of m_2 which should be used in any particular system. On a heuristic basis it might be argued that the introduction of second-derivative control is in effect the introduction of inertia. Negative inertia as afforded by the use of the negative sign with m_2 might therefore appear to be preferable in order to decrease the magnitude of the apparent inertia of the system. On the basis of this argument a coefficient m_2 equal in magnitude to J_0 and used with the negative algebraic sign might appear to provide the optimum adjustment. It should be clear, however, that values of m_2 greater than J_0 used in conjunction with the negative algebraic sign give negative values of J_0, make the system unstable, and hence are barred. Unfortunately, this argument is inadequate for appraising quantitatively the benefits of specific amounts of second-derivative response.

The work involved in preparing quantitative data for this problem can be simplified without much loss generality of the results by again assuming output damping to be zero, thereby making α_2 and the steady-state error zero. If both l_2 and k_2 are held constant as $\pm m_2$ is varied, it follows readily from Equations [39] that ζ_2 and ω_{n2} are proportional to $\sqrt{\sigma_2}$, and hence dependent upon $\pm m_2$. Since the scales of ordinate and abscissa in Fig. 6 involve ω_{n2}, Equations [41a] and [42a] are not in a particularly convenient form for studying the effects of varying amounts of second-derivative control. It is possible, however, to express the error in a form which does not involve ω_{n2} by using a new characteristic time τ_2' defined as

$$\tau_2' = \frac{f_0 \pm l_2}{k_2} = \frac{2\zeta_2}{\omega_{n2}}$$

giving

$$\tau_2' = 2\zeta_2^2\tau_2 \ldots\ldots [45]$$

In terms of this new characteristic time a dimensionless form of the error equation convenient for studying the effect of varying $\pm m_2$ is

$$\frac{\epsilon(t)}{\omega_i\tau_2'} = \frac{1}{2\zeta_2\sqrt{1-\zeta_2^2}} e^{-\frac{2\zeta_2^2 t}{\tau_2'}} \sin 2\zeta_2\sqrt{1-\zeta_2^2}\,\frac{t}{\tau_2'} \ldots [41b]$$

for the oscillatory case and

$$\frac{\epsilon(t)}{\omega_i\tau_2'} = \frac{t}{\tau_2'} e^{-\frac{2t}{\tau_2'}} \ldots\ldots [42b]$$

for the critically damped case.

Fig. 7 gives a plot of a family of curves of the dimensionless quantity $\frac{\epsilon(t)}{\omega_i\tau_2'}$, as a function of the dimensionless time $\frac{t}{\tau_2'}$, for various values of ζ_2. Load torque and coulomb friction are assumed zero in addition to output damping being assumed zero. Neither the ordinate nor the abscissa variables are here functions of $\pm m_2$. Therefore the family of curves indicates directly the true relative times of duration of the transient and the true relative magnitudes of the peak transient error for the assumed values of ζ_2. It must be remembered, however, that variations in the magnitude or the algebraic sign used with the component of second-derivative response of the controller vary ζ_2, since ζ_2 is proportional to $\sqrt{\sigma_2}$. Changes in controller design which affect the second-derivative response are nevertheless readily transferred into quantitative data giving the changes in the performance of the system. The procedure is to compare the response indicated by the curve for the damping ratio in effect before the design is changed, say, ζ_{2a}, and the curve for a ζ_2 equal to $\zeta_{2a}\sqrt{\sigma_2}$. For example, assume that a particular design has $\zeta_{2a} = 0.5$. Then assume that a proposed design modification will change $\pm m_2$ by an amount sufficient to increase σ_2 by a factor of 4. The system then has $\zeta_2 = \sqrt{4}\zeta_{2a} = 1.0$, and the effect of the design change on the relative magnitudes of peak transient error and the times of duration of the transient is shown quantitatively by the curves for $\zeta_2 = 0.5$ and $\zeta_2 = 1.0$, respectively. At first glance these results may appear to be strange for they show that a system originally underdamped and having a rather large peak error can be made to have a substantially smaller peak error, be less oscillatory, and be substantially faster in response by increasing σ_2.

The data in Figs. 6 and 7 serve (*a*) to confirm the heuristic conclusion that the negative algebraic sign should be used with m_2; (*b*) to show that the magnitude of m_2 must be substantial if a substantial decrease in the time of the duration of the transient be brought about; and (*c*), that operation with less than critical damping justifies consideration. It should be remembered, however, that it is probably undesirable to approach too close to the condition in which $\sigma_2 > 10$, that is, $m_2 = 0.9\ J_0$, because of the likelihood that the system will become unstable if accidentally J_2 becomes negative.

The optimum damping ratio for use in any application depends, of course, on the magnitude of the transient departure from the steady-state error that is permissible. Since there is likely to be both viscous and coulomb friction in the output member, the steady-state error is actually finite. A net damping ratio such that $0.6 < \zeta_2 < 0.8$ is then generally satisfactory from the standpoint of small overshoot and preferable from the standpoint of speed of response, because the error is brought within the steady-state operating band about as rapidly as is practicable.

On the basis of the foregoing arguments and the data in Figs. 6 and 7 there should be no doubt about the economic value of introducing a component of first-derivative response into the controller, since by doing so the cost and difficulty of adding damping to the output member are eliminated, the unusually large power rating required of the servomotor, and the ridiculously low over-all efficiency of such a system are obviated. The data herein given permit the designer to evaluate quantitatively the relative merits of first- and second-derivative response when designing a specific system. Considering the practical difficulties that are encountered when the task of designing a controller to yield a second-derivative response with high fidelity is undertaken, there are, no doubt, many instances where the returns hardly justify the costs. Obviously circumstances alter cases, and in many important control applications it is entirely proper to pay a rather large premium to decrease the time of duration of the transient or the magnitude of the peak transient error by a factor of even 2 or less. At such times only a moderate amount of control response, which even then only approximates second-derivative control, may prove to be extremely valuable.

Transient solutions for angle or torque disturbances applied to a system with a type 2 controller are readily obtained by the procedure given. For the boundary conditions at the instant immediately following the application of torque or angle, that is, at $t = 0^+$ such that

$$\epsilon = \theta_i;\ \theta_0 = \text{zero};\ p\epsilon = p\theta_i = p\theta_0 = \text{zero}$$

$$p^2\epsilon = -p^2\theta_0 \text{ and } p^2\theta_i = \text{zero}$$

the time solutions are identical for those obtained for a system with a type 1 controller with the exception that ζ_2 and ω_{n2} replace ζ_1 and ω_{n1}, respectively. The curves in Fig. 5 therefore apply to a type 2 controller if ζ_2 and ω_{n2} are used instead of ζ_1 and ω_{n1}.

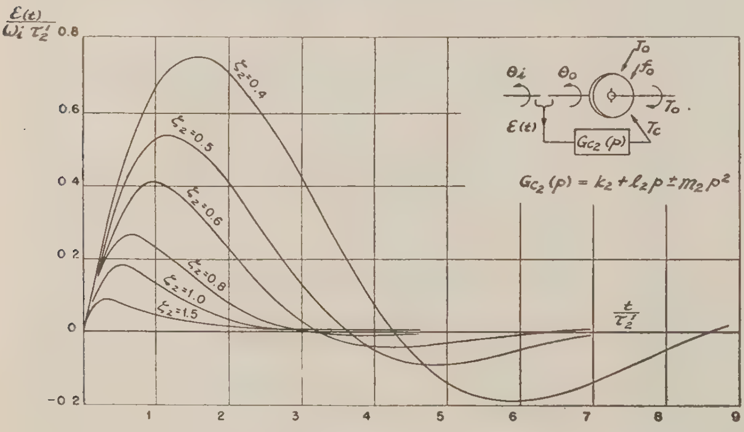

FIG. 7 DIMENSIONLESS TRANSIENT ERROR CURVES FOR A SERVOMECHANISM WITH A TYPE 2 CONTROLLER WITH $\alpha_2 = 0$ AND WITH l_2 CONSTANT, WHEN SUBJECTED TO A SUDDENLY APPLIED INPUT VELOCITY ω_i

8 CONTROLLERS TO COUNTERACT COULOMB OR LOAD TORQUES

In control applications where the output member is principally inertia, an acceptable steady-state error is frequently obtained by decreasing the viscous and coulomb frictions in the output member to a practical minimum and introducing derivative control to establish transient stability. At such times type 2

control is adequate. However, in applications such as precision machine-tool control, calculating machine servomechanisms, and so forth, exceedingly precise performance is often demanded even when the output member is required to operate against a substantial disturbing or load torque T_L, in addition to coulomb friction. At such times it is really difficult to obtain highly precise performance.

Although only mechanical systems have been discussed thus far, it should be remembered that where the mechanisms involve electrically operated elements or hydraulic elements, resistance in the electric circuits or fluid circuits is just as effective in causing steady-state error as mechanical viscous friction. Similarly, the induced voltage of an electromagnetic machine, or the operating fluid pressure of a hydraulic system, and similar phenomena, usually cause effects analogous to those of an output load torque. Also, magnetic hysteresis in the magnetic circuits of electromagnetic machines, and dielectric hysteresis in the dielectric of capacitive elements, are analogous to coulomb fricton and equally undesirable. Thus there is inherently a definite limit to the degree of precision with which almost any servomechanism having type 1 or type 2 controller can operate.

If means to combat these difficulties are to be devised they can come about only as a result of a modification to the controller, since the controller characteristic is really the only design variable. Accordingly the basic-error equation will again be examined, but this time with a view to devising for the controller operator $C(p)$ an expression that will insure not only a stable and rapid system, but one which will counteract the effects of coulomb or load torques.

For the system under consideration the error equation is, by analogy with Equation [9]

$$\epsilon(t) = \frac{(J_0p + f_0)\omega_i(t) + F(\omega) + T_L(t)}{J_0p^2 + f_0p + C(p)} \quad \text{[46]}$$

where the symbol F signifies coulomb friction torque which is a function of the velocity of the output shaft. Since the direction of this torque reverses as the direction of rotation reverses, Equation [46] is nonlinear and is difficult to handle mathematically. If, however, it is assumed that coulomb friction can be represented as a constant torque which appears only after t = zero, the analysis becomes relatively straightforward and the results are still sufficiently general to be useful. On this basis the error equation can be written for a velocity input as

$$\epsilon(t) = \frac{(J_0p + f_0)\omega_i(t) + F + T_L}{J_0p^2 + f_0p + C(p)} \quad \text{[47]}$$

For optimum performance it is desirable that the controller counteract the results of F and T_L during the period of transient operation as well as during the steady state. The transient-error behavior is indicated to a considerable extent by the nature of the roots of the denominator of Equation [47]. The steady-state error for a constant disturbance, however, is given directly by the foregoing error equation if p is put equal to zero after the equation is converted to the ratio of two polynomials. Therefore from the mathematical viewpoint at least, the steady-state error would be made zero if the controller were modified so that the law of control would have the effect of multiplying F and T_L by p in Equation [47]. Then when this is done an attempt might be made to adjust the magnitudes of the resulting function $C(p)$ to give the desired transient performance. Thus both objectives would be achieved.

The process of synthesizing a controller operator $C(p)$ which would achieve these objectives can logically start by multiplying the numerator and denominator of Equation [47] by p. The error equation then has the form

$$\epsilon(t) = \frac{p(J_0p + f_0)\omega_i(t) + p(F + T_L)}{p[J_0p^2 + f_0p + C(p)]} \quad \text{[48]}$$

The steady-state error is now zero, provided the denominator is a polynomial containing a constant term. The restrictions that may be imposed on the operator $C(p)$ to achieve satisfactory transient response are that the roots of the polynomial

$$\left.\begin{array}{ll} & p[J_0p^2 + f_0p + C(p)] = 0 \\ \text{or} & \\ & J_0p^3 + f_0p^2 + pC(p) \;\;= 0 \end{array}\right\} \quad \text{[49]}$$

have substantial negative real parts and, if complex, have magnitudes of the imaginary parts that provide reasonable periods for the oscillation of the system. Since one of the criteria to be satisfied in order for the roots to have negative real parts is that the polynomial have all the coefficients of the same algebraic sign, the simplest form for the function $pC(p)$ is

$$pC(p) = ap + b \quad \text{[50]}$$

where a and b are positive real quantities.

The result of this analysis has been to show that in order to counteract constant output torques a controller is required whose response is proportional to the error plus the time integral of the error. Actually, it has been known for some time that this response is of value in control problems of the type herein discussed, since it was demonstrated by Minorsky (5) as early as 1922 and treated by Mitereff (23) in 1935.

To those already familiar with automatic-control theory, moreover, it may appear that the foregoing analysis amounts to much ado about nothing This really is not so, however, for while to some persons it may have been obvious after a little thought that the inclusion of an integral term in the controller response would achieve the results desired in the simple example cited, it is not always so easy to reach reliable conclusions in more complicated control problems. On the other hand, the procedure here presented whereby the form of controller characteristic is deduced (*a*) by first examining the error equation with a view to seeing what properties it must have to yield the solution desired and (*b*) by manipulating it mathematically to give it these properties, is quite powerful and widely applicable in control problems. It readily yields data that are directly interpretable in terms of the design of a suitable controller.

In the analysis which follows the integral-plus-proportional controller is referred to as type 3. For the purposes of generality, and also in the interests of improved transient response of a servomechanism with this type of controller, the general form of the operator for type 3 control is taken as

$$C_3(p) = k_3 \pm l_3p \pm m_3p^2 + \frac{n_3}{p} \quad \text{[51]}$$

where k_3, l_3, m_3, and n_3 are all positive real quantities and, except for l_3 and m_3, they can be associated only with the positive algebraic sign because of stability criteria.

The substitution of $C_3(p)$ from Equation [51] in Equation [48] gives for the error of a servomechanism with a type 3 controller

$$\epsilon(t) = \frac{(J_0p^2 + f_0p)\omega_i(t) + p(F + T_L)}{J_3p^3 + f_3p^2 + k_3p + n_3} \quad \text{[52]}$$

where

$$J_3 = J_0 \pm m_3 \quad \text{and} \quad f_3 = f_0 \pm l_3 \quad \text{[53]}$$

9 Transient Solution of Servomechanisms With Type 3 Controller

Equation [52] does not readily yield a solution adaptable to simple graphical presentation from the design standpoint, because

of the large number of design variables and the complexity resulting from the third-order denominator. As Equation [52] stands, however, it shows that the steady-state error is zero for either a constant input angle, a constant input velocity, or a constant disturbing torque on the controlled member. However, if the input undergoes a constant acceleration, $p\omega_i$, the steady-state error is

$$\epsilon_{ss} = \frac{f_0}{n_3}(p\omega_i) \qquad [54]$$

The question of an ideal versus a nonideal controller arises when a solution of Equation [52] is attempted for a step-function disturbance of angle or velocity. It is seen by inspection of Equation [52] written in the form of a step function of angle, that the operational solution at $t = 0$ for the equation as it stands is

$$\epsilon(0) = \frac{J_0}{J_3}\theta_i$$

This result can be obtained by taking the limit of the error equation as p tends to infinity. For this value of $\epsilon(0)$ to occur the output member would have to undergo a finite displacement in zero time. No physical controller can accomplish this with an output member that comprises mass because the mass cannot be moved in zero time by only a finite torque. This argument is given only briefly for simplicity. If the differential equation of Equation [52] is solved by classical methods subject to physically realizable boundary conditions at $t = 0$, and especially that $\epsilon(0) = \theta_i(t)$ at $t = 0$, the solution will be correct. Alternatively, if methods of formulating the equation such as those of LaPlace (9) are followed, the term J_3 appears in the numerator of the error equation, and not J_0. For these reasons the liberty is taken here of writing the error equation in corrected operational form for a velocity disturbance as

$$\epsilon(t) = \frac{(J_3p^2 + f_0p)\omega_i + p(F + L)}{J_3p^3 + f_3p^2 + k_3p + n_3} \qquad [55]$$

and for an angle disturbance as

$$\epsilon(t) = \frac{(J_3p^3 + f_3p^2)\theta_i + p(F + L)}{J_3p^3 + f_3p^2 + k_3p + n_3} \qquad [56]$$

It is desirable to attain some simplification of Equations [55] and [56] before attempting a solution. Simplification occurs, partially at least, by writing the equation in a dimensionless form. Two forms have been found useful. One follows from a method originally indicated by Weiss (10). The other follows by recognizing that the factors of a cubic equation can be written as a quadratic times a real root. Both forms are helpful in design studies. Weiss has prepared useful charts (10) giving the roots of the cubic in forms that aid many design problems. Liu (11) and Evans (12) have prepared charts in the form that is of special significance when the cubic is written as a quadratic factor and a real root. These charts have been found somewhat more useful than those of Weiss, because they permit the solution to be written in terms of damping ratios and undamped natural frequencies, with the result that the data already given in dimensionless form for type 1 and type 2 servos can be made immediately applicable semiquantitatively simply by matching characteristics of the oscillatory components for ζ and ω_n.

The dimensionless form that follows from the work of Weiss writes the denominator of the type 3 servo

$$p^3 + \frac{f_3}{J_3}p^2 + \frac{k_3}{J_3}p + \frac{n_3}{J_3} = 0 \qquad [57]$$

in the form

$$p^3 + 2\zeta_c\omega_n p^2 + \omega_n^2 p + S\omega_n^3 = 0 \qquad [58]$$

where the terms ζ_c, ω_n, and S are merely defined by applying the approach used for nondimensionalizing the quadratic, and in the case of ζ_c and ω_n do not represent a damping ratio or undamped natural period. By definition

$$\left.\begin{aligned} S &= 2\zeta_3\gamma_3 = \frac{n_3}{k_3}\sqrt{\frac{J_3}{k_3}} \\ \zeta_c &= \frac{f_3}{2\sqrt{J_3k_3}}, \quad \omega_n = \sqrt{\frac{k_3}{J_3}} \end{aligned}\right\} \qquad [59]$$

where γ_3 comes from a stability ratio $\frac{J_3n_3}{f_3k_3}$ using Rouths' stability criteria.

The alternate form, as used by Liu and Evans, writes the denominator as

$$(p + \xi\omega_{nq})(p^2 + 2\zeta_q\omega_{nq}p + \omega_{nq}^2) = 0 \qquad [60]$$

where ζ_q and ω_{nq} now represent specifically the damping ratio and undamped natural period of the quadratic factor or oscillatory component.

The relations between S, ζ_c, ω_n and ξ, ζ_q, and ω_{nq} are

$$(2\zeta_q + \xi)\omega_{nq} = 2\zeta_c\omega_n = \frac{f_3}{J_3} \qquad [61a]$$

$$(2\zeta_q\xi + 1)\omega_{nq}^2 = \omega_n^2 = \frac{k_3}{J_3}; \text{ and } \xi\omega_{nq}^3 = S\omega_n^3 = \frac{n_3}{J_3} \qquad [61c]$$

An interesting application of the merits of these so-called dimensionless forms of equations results from a study of the following problem: Assume that integral response is to be introduced into a controller which initially has a ratio of output damping to total damping $\alpha_3 = 0.2$ and a damping ratio ζ_2 which is also $\zeta_c = 0.8$. Assume that it is desired to investigate the form of the transient response to a suddenly applied velocity or angle as integral response is introduced into the controller in amounts represented by $S = 0, 0.2, 0.4$. Since the servo without integral control has already been studied in terms of curves using $\omega_n t$ as the dimensionless time, see Figs. 4, 5, and 6, the same form of dimensionless time can again be used to advantage.

Table 1 shows the dimensionless solution for the error equation of the form

$$\epsilon(t) = \frac{[p^2 + \omega_{nq}\alpha_3(2\zeta_q + \xi)p]\omega_i}{(p + \xi\omega_{nq})(p^2 + 2\zeta_q\omega_{nq}p + w_{nq}^2)} \qquad [55a]$$

$$\epsilon(t) = \frac{[p^3 + \omega_{nq}(2\zeta_q + \xi)p^2]\theta_i}{(p + \xi\omega_{nq})(p^2 + 2\zeta_q\omega_{nq}p + \omega_{nq}^2)} \qquad [56a]$$

where load torques are neglected.

Figs. 8 and 9 show the solution of $\frac{\epsilon(t)\omega_n}{\omega_i}$ and $\frac{\epsilon(t)}{\theta_i}$ as a function of $\omega_n t$.

The numerical solutions were obtained using the cubic chart prepared by Liu (11). Values of ζ_c and S are known and are the values used to enter the chart for determining the values of ζ_q, ξ. Finally ω_{nq} is computed from S and ξ using the relation

$$\omega_{nq} = \left(\frac{S}{\xi}\right)^{1/3}$$

One observation predominates from an inspection of Figs. 8 and 9, namely, that a system which initially is well damped and

TABLE 1 RESPONSE OF A SERVOMECHANISM WITH A TYPE 3 CONTROLLER

For a suddenly applied input velocity disturbance ω_1

$$\varepsilon(t) = \frac{(J_3p^2 + f_0p)\,\omega_1}{J_3p^3 + f_3p^2 + k_3p + n_3}$$

$$\varepsilon(t) = \frac{\left[p^2 + a_3(2\zeta_q + \xi)\,\omega_{nq}\right]\omega_1}{(p + \xi\omega_{nq})\,(p^2 + 2\zeta_q\omega_{nq}p + \omega_{nq}^2)}$$

$$\frac{\varepsilon(t)\omega_n}{\omega_1} = k_1\varepsilon^{-\xi\omega_{nq}t} + k_2\varepsilon^{-\zeta_q\omega_{nq}t}\cos\left(\omega_{nq}\sqrt{1-\zeta_q^2}\,t + \theta\right)$$

$$k_1 = \frac{\sqrt[3]{\xi}\left[(2\zeta_q + \xi)\,a_3 - \xi\right]}{\sqrt[3]{S}\left[\xi^2 - 2\zeta_q\xi + 1\right]}$$

$$k_2 = \frac{\sqrt[3]{\xi}\sqrt{a_3^2\,(2\zeta_q + \xi)^2 - 2a_3\zeta_q\,(2\zeta_q + \xi) + 1}}{\sqrt[3]{S}\sqrt{(1-\zeta_q^2)\,(\xi^2 - 2\zeta_q\xi + 1)}}$$

$$\theta = \tan^{-1}\frac{\zeta_q - a_3\,(2\zeta_q + \xi)}{\sqrt{1-\zeta_q^2}} - \tan^{-1}\frac{\sqrt{1-\zeta_q^2}}{\xi^2 - \zeta_q}$$

For a suddenly applied input angular disturbance θ_1

$$\varepsilon(t) = \frac{(J_3p^3 + f_3p^2)\,\theta_1}{J_3p^3 + f_3p^2 + k_3p + n_3}$$

$$\varepsilon(t) = \frac{\left[p^3 + (2\zeta_q + \xi)\,\omega_{nq}p^2\right]\theta_1}{(p+\xi\omega_{nq})\,(p^2 + 2\zeta_q\omega_{nq}p + \omega_{nq}^2)}$$

$$\frac{\varepsilon(t)}{\theta_1} = k_1\varepsilon^{-\xi\omega_{nq}t} + k_2\varepsilon^{-\zeta_q\omega_{nq}}\cos\left(\omega_{nq}\sqrt{1-\zeta_q^2}\,t + \theta\right)$$

$$k_1 = \frac{-2\zeta_q\xi}{(\xi^2 - 2\zeta_q\xi + 1)}$$

$$k_2 = \frac{\sqrt{(1+\xi\zeta_q)^2 + (\xi\sqrt{1-\zeta_q^2})^2}}{\sqrt{1-\zeta_q^2}\sqrt{\xi^2 - 2\xi\zeta_q + 1}}$$

$$\theta = \tan^{-1}\frac{1+\zeta_q\xi}{\xi\sqrt{1-\zeta_q^2}} - \tan^{-1}\frac{\sqrt{1-\zeta_q^2}}{\xi - \zeta_q}$$

$$J_3 = J_o \pm m_3 \qquad G_c(p) = k_3 \pm \ell_3p \pm m_3p^2 \pm \frac{n_3}{p}$$

$$f_3 = f_o \pm \ell_3$$

$$\sigma_3 = \frac{J_o}{J_3}$$

$$a_3 = \frac{f_o}{f_3}$$

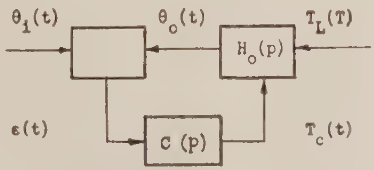
$$\zeta_3 = \frac{f_3}{2\sqrt{k_3J_3}}$$

$$2\zeta_3\,\omega_n = (2\zeta_q + \xi)\,\omega_{nq}$$

$$\omega_n^2 = (2\zeta_q\xi + 1)\,\omega_{nq}^2$$

$$S\omega_n^3 = \xi\omega_{nq}^3$$

$$\omega_{n3} = \sqrt{\frac{k_3}{J_3}}$$



fast becomes more oscillatory and faster as integral control is increased. To procure a reduction in the degree of oscillation, it is apparent immediately that ζ_q must be increased because this parameter controls the oscillatory component. A valuable feature of the dimensionless study using curves such as those prepared by Liu is now recognized because the curves of either Weiss or Liu quickly show the manner in which ζ_c or S must be varied to give the desired ζ_q. Although these parameters are dimensionless, their transformation into real parameters is simple so that actually the curves directly give quantitative data. It is interesting to note that there is always a value of ζ_c beyond which little improvement in ζ_q is obtained, thus necessitating a review of the whole design problem.

10 Systems Involving Energy Storage Elements in Controller or Output

In the preceding analysis the controller has been assumed to be an element that correctly obeys the law of control as given for $C(p)$. While this condition is approximated in many systems, certain inherent properties of physical elements cause the introduction of other considerations into the analysis. For example, the output stages of controllers, which involve power amplification or the servomotor driving the output member, will frequently include (*a*) inductance if it is electromagnetic, (*b*) elastance of oil lines or inertia of valves or pistons if it is hydraulic, (*c*) elastance of air lines if pneumatic. Thus energy storage and energy dissipation occur throughout the system with attendant so-called "response delays." The over-all controller response $T_c(t)$ is then not in phase with the signal that actually initiates the action of the servomotor elements, as is implied by Equation [12].

When the response of any element is fast compared with the system response, its response may be considered instantaneous because the energy storage can usually be neglected. When its response becomes comparable with the speed of system response it is necessary to modify the operator for the controller to introduce the effects of these energy storage elements into the analysis. To do this let a new operator $D(p)$ be used to describe the over-all performance of the controller-servomotor combination, where $D(p) = C(p)\,A(p)$ and in which $C(p)$ characterizes only the portion of the controller that receives the error signal $\epsilon(t)$ and operates on it to yield the proportional, derivative, or integral components of control, and $A(p)$ takes account of the energy storage or "response delay" in the controller output or the servomotor. Equation [2] now becomes $T_c(t) = C(p)\,A(p)\,\epsilon(t)$ and the over-all system operator from Equation [4*a*] becomes

$$1 + C(p)\,A(p)\,H_0(p)$$

As an illustration, consider that the controller comprises a

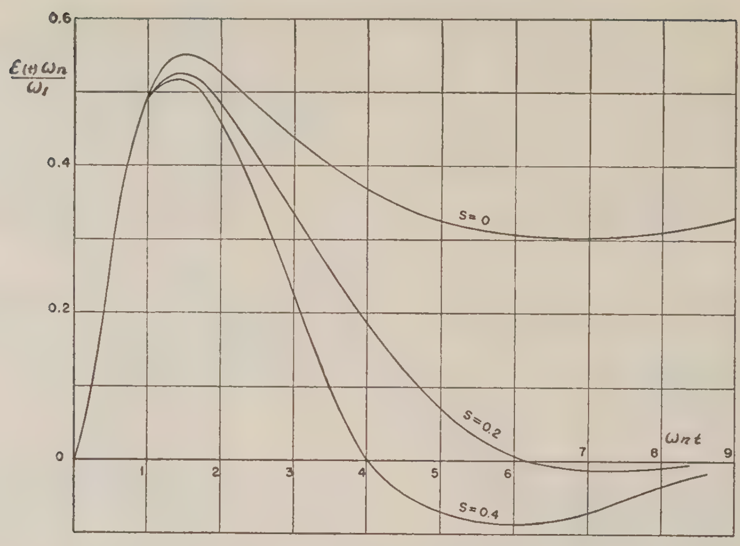


Fig. 8 Transient Error Curves for a Velocity Disturbance Showing Effect of Introducing Integral Control Into a Type 2 Servomechanism for Which Initially $\zeta_2 = 0.8$ and $\alpha_2 = 0.2$
(Amount of integral control is given by $S = 0$, 0.2, and 0.4.)

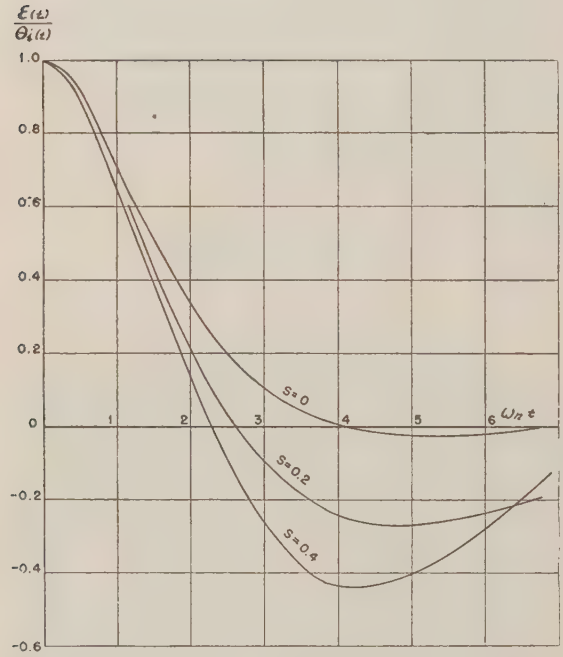

Fig. 9 Transient Error Curves for an Angle Disturbance, Showing Effect of Introducing Integral Control Into a Type 2 Servomechanism for Which Initially $\zeta_2 = 0.8$ and $\alpha_2 = 0.4$

vacuum-tube amplifier that energizes the field of a generator supplying an electric servomotor. The operator $C(p)$ characterizes the vacuum-tube amplifier field circuit of the generator. If it is assumed that the build-up field flux in the generator is substantially in phase with the grid signal on the amplifier, the principal response lag will be in armature current. The build-up of servomotor torque will lag the generator-field flux because of inductance L_a and resistance R_a of the two armatures. The operator $A(p)$ characterizing the servomotor would then have the form

$$A(p) = \frac{K}{L_a p + R_a}$$

Thus for the system considered in Fig. 3, Equation [9] would take the form

$$\epsilon(t) = \frac{L_a p + R_a}{K(J_0 p^2 + f_0 p)(L_a p + R_a) + C(p)}\,[(J_0 p + f_0)\omega_i(t) + T_0(t)]$$

A typical block diagram for a system involving several ele-

ments, each with response lag, is shown in Fig. 10. The over all system operator for such a system is

$$1 + \left[\begin{matrix}\text{Controller}\\ \text{Operator}\end{matrix}\right]\left[\begin{matrix}\text{Preamplifier}\\ \text{Operator}\end{matrix}\right]\left[\begin{matrix}\text{Servomotor}\\ \text{Operator}\end{matrix}\right]\left[\begin{matrix}\text{Output}\\ \text{member}\\ \text{Operator}\end{matrix}\right]$$

which leads to a characteristic equation involving high powers of p for which the labor in getting transient solutions may be considerable. The matter is discussed in section 13.

11—Systems With Output Feedback

In many servomechanisms the error signal given by the error-measuring means is of such a form that it cannot even be easily differentiated once to give good control signals for stabilizing purposes, as previously discussed for a type 2 system, let alone be differentiated twice. In some cases the particular embodiment that the servomechanism takes makes it undesirable to employ

derivative networks. Frequently the error is of such form that good techniques for giving its time rate of change do not exist.

Methods of control that will yield the desired stability or dynamic performance without error differentiation therefore become necessary. The method most commonly used is to feedback (14) to the input a signal that is some function of the response of the servo output, or a response just ahead of the output. Fig. 11 shows the block diagram for a typical system involving

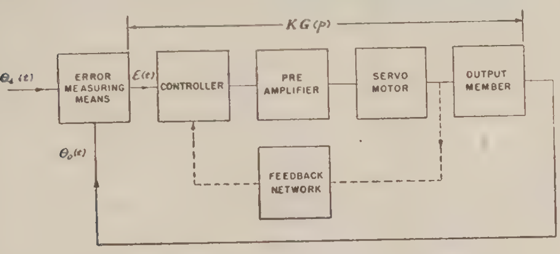

FIG. 11 BLOCK DIAGRAM FOR SERVOMECHANISM COMPRISING SEVERAL ENERGY STORAGE ELEMENTS IN CASCADE AND FEEDBACK WITHIN CLOSED LOOP

feedback. The particular functional relationship between the output and the feedback signals is established by an arrangement of elements inserted specifically for the purpose, and for which a feedback operator is known or can be deduced. No standard rule can be given for the form of the operator used for the feedback (14) since the choice of derivative, integrative, or even the number of feedback elements becomes a function of the specific application for which the servomechanism is intended.

As a general rule the introduction of feedback networks adds energy-storage elements into the system and increases the powers of p in the characteristic equation. By the application of the operator relations for the resulting network the over-all system operator becomes for Fig. 11

$$1 + \frac{\begin{bmatrix}\text{Controller}\\\text{Operator}\end{bmatrix}\begin{bmatrix}\text{Preamplifier}\\\text{Operator}\end{bmatrix}\begin{bmatrix}\text{Servomotor}\\\text{Operator}\end{bmatrix}\begin{bmatrix}\text{Output}\\\text{Operator}\end{bmatrix}}{1 - \begin{bmatrix}\text{Controller}\\\text{Operator}\end{bmatrix}\begin{bmatrix}\text{Preamplifier}\\\text{Operator}\end{bmatrix}\begin{bmatrix}\text{Servomotor}\\\text{Operator}\end{bmatrix}\begin{bmatrix}\text{Feedback}\\\text{Operator}\end{bmatrix}}$$

12 TRANSIENT ANALYSIS OF SYSTEMS INVOLVING HIGH-ORDER CHARACTERISTIC EQUATIONS

In the systems of the types discussed in sections 10 and 11 the characteristic equations invariably involve high powers of p. The transient analysis then becomes complicated because of (a) the difficulty of determining the parameters of all elements such as inertia, elastance, inductance, damping, amplification, torque gradient, and so forth, for each element in the system and (b) the labor of getting the roots and the time solutions to problems involving characteristic equation of high orders. While the analysis may be classified as tedious, the synthesis of controllers and feedback elements by the transient methods is difficult because the coefficients of the powers of p in the characteristic equation are a heterogeneous arrangement of many of the parameters of the elements of the system. Thus even when the work of obtaining the transient solution has been completed it is difficult to identify any particular element in the system that must be changed to cause any preselected modification in system behavior.

A qualitative knowledge of the transient behavior that is useful for many purposes may, however, be obtained by recognizing that the characteristic equation can be factored into the product of quadratic factors as follows

$$p^n + bp^{n-1} + cp^{n-2} + \ldots = (p^2 + 2\zeta_a\omega_{na}p + \omega_{na}^2)(p^2 + 2\zeta_b\omega_{nb}p + \omega_{nb}^2)\ldots(p + a)$$

Each quadratic factor contributes to a mode of oscillation in the solution having damping ratios ζ_a, ζ_b, ζ_c and undamped natural frequency ω_{na}, ω_{nb}, ω_{nc}, and so forth. Then by the principle of linear superposition the servomechanism response is the sum of the responses attributed to the specific modes a, b, c, etc. Thus for each component of error response the duration of the transient is given qualitatively by reference to the types of solutions given in the body of the paper for simple quadratics, and the relative magnitudes of the transients can often be approximated from the observation that the higher the magnitude of the root the smaller the coefficient of the time solution involving that root. It should be remembered that the parameters of the several elements in a system are not always known to high degrees of accuracy, and that approximate or graphical methods (11, 12, 19, 20, 22) that give the roots to the characteristic equations[5] to a few significant figures are justifiable and timesaving.

Because of the difficulties mentioned the transient method of analysis of complicated systems becomes most valuable as an aid to the visualization of the performance of a system rather than an aid in its design. If a designer has carried out the analysis of the dynamic performance based upon transient studies he can correlate the information with the actual performance if he gives any physical system a transient disturbance by any one of several means readily available to him and then observes or measures the response.

The next section of the paper treats a method of analysis that is particularly useful in the design of complicated systems. This method is sometimes termed the transfer-loci method and is based upon the frequency-response characteristic of the servomechanism.

13 FREQUENCY RESPONSE OF A SERVOMECHANISM

The difficulties of analyzing or synthesizing a complex servomechanism or automatic-control system by the transient method of analysis early became apparent to several investigators and a search was made for a more powerful and less cumbersome method of analysis. During this search it was natural to examine the methods employed in electrical analysis since complex electrical circuits had been analyzed and synthesized effectively for many years. Circuit analysis has been effectively carried out for some time through the study of its frequency-response characteristics. It appeared that the same general approach might prove effective in servomechanism design. Nyquist had developed a powerful means of determining the stability of feedback amplifiers through a study of its frequency-response characteristics and the similarity between feedback amplifiers and servomechanisms had been recognized. In 1942 Harris (21) pointed out that genuine improvements in design technique might result from applying the frequency-response method of analysis to servomechanism design, and in 1943 Hall (13) presented a thorough treatment of servomechanism analysis and synthesis by frequency-response methods. As a result of these investigations the frequency-response approach to servomechanism analysis has been developed into a powerful tool. Most of the remainder of the present paper is adapted from the paper by Hall (13).

The term "frequency-response characteristic," when applied to a mechanism, refers to the relationship between the input and the output of that mechanism when the input is a sinusoidal function of time. In servomechanism terminology, if $\theta_i(t)$ is the input and $\theta_0(t)$ is the output of a servomechanism (see Fig. 2) then if

[5] For a summary of graphical and analytical methods of obtaining the roots to characteristic equations, see Appendix C of the book by Ed S. Smith (22).

$$\theta_i(t) = A \sin \omega t \quad [57]$$

and A is small it will always be true that

$$\theta_0(t) = B \sin (\omega t + \phi) \quad [58]$$

In these equations A is known as the amplitude of the input, B is known as the amplitude of the output, ω is the angular frequency of motion of $\theta_i(t)$ and $\theta_0(t)$ (equal to $2\pi f$ where f is in cycles per second), and ϕ is the relative phase angle between $\theta_i(t)$ and $\theta_0(t)$.

The amplitude ratio B/A, and the phase angle ϕ, when determined as functions of angular frequency ω, comprise the frequency-response characteristic of the servomechanism.

As just shown, the relationship between $\theta_0(t)$ and $\theta_i(t)$, when $\theta_i(t)$ is a sinusoidal function of time, is specified by a magnitude (B/A) and an angle (ϕ). These two quantities can be considered as the defining properties of a vector whose amplitude is (B/A) and whose phase is ϕ. Thus it is frequently stated that a vector relationship exists between $\theta_i(t)$ and $\theta_0(t)$, when $\theta_i(t)$ varies sinusoidally with time. This vector relationship is represented symbolically by $\frac{\theta_0}{\theta_i}(j\omega)$ in which $j(=\sqrt{-1})$, itself, is generally thought of as a vector and emphasizes the vector properties of the ratio. The vector ratio, $\frac{\theta_0}{\theta_i}(j\omega)$ is characterized by an amplitude

$\left|\frac{\theta_0}{\theta_i}(j\omega)\right|$, and a phase, arc $\left[\frac{\theta_0}{\theta_i}(j\omega)\right]$

The preceding development is briefly summarized as follows: If in a servomechanism

$$\theta_i(t) = A \sin \omega t \quad [57]$$

then

$$\theta_0(t) = B \sin (\omega t + \phi) \quad [58]$$

By definition the frequency response is denoted by $\frac{\theta_0}{\theta_i}(j\omega)$. The amplitude response is given by

$$\left|\frac{\theta_0}{\theta_i}(j\omega)\right| = \frac{B}{A} \quad [59]$$

and the phase response is represented by

$$\text{arc}\left[\frac{\theta_0}{\theta_i}(j\omega)\right] = \phi \quad [60]$$

The amplitude and phase response curves of a typical servomechanism are illustrated in Fig. 12.

The curves in Fig. 12 may be obtained (*a*) by calculation, if the constants of an actual or proposed design are available, or (*b*) by measurement, if the servomechanism itself is available. The frequency-response characteristic is measured by moving the input sinusoidally at a fixed amplitude but at various frequencies. At each frequency the amplitude of the output and its phase relation to the input motion is measured. The ratio of the amplitudes, plotted for each frequency, yields the first of the curves in Fig. 12. The phase difference between the input and output plotted for various frequencies gives the second of the curves in Fig. 12. The curves in Fig. 12 are readily calculated if the constants of the system and the differential equation relating the output to the input are known. The calculation is effected by replacing the operator p by the frequency operator $j\omega$ (where $j = \sqrt{-1}$) and applying conventional vector arithmetic.

The frequency response of a servomechanism may be closely correlated with its transient response. Important natural frequencies in the transient response are indicated by peaks in the amplitude-response curve. The magnitudes of the peaks of the amplitude response are measures of the relative damping of the natural frequencies of the transient response. The frequency band over which the amplitude response has a substantially constant magnitude is a measure of the speed of response to transients, since a high natural frequency (and therefore a high speed of response) is linked with a high resonant frequency in the amplitude response. When, as just indicated, the frequency-response characteristic is correlated with the transient-response characteristic, the former becomes a powerful means of analysis. The correlation between the sinusoidal and transient characteristics is illustrated by comparing the transient and frequency response of a simple servomechanism, representable by a second-order differential equation. Such a servomechanism comprises a servomotor with a moment of inertia and damping and whose output torque is proportional to the error.

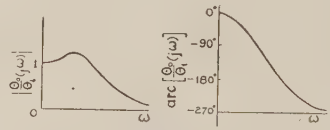

Fig. 12 Amplitude- and Phase-Response Curves of a Typical Servomechanism

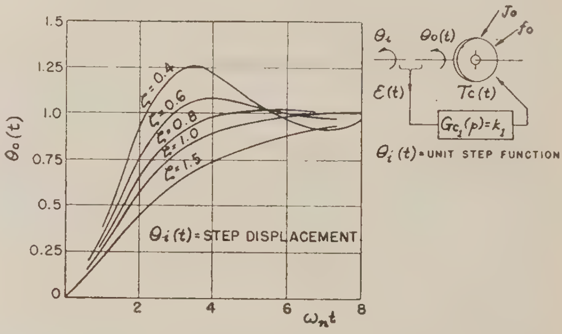

Fig. 13 Transient Responses of a Second-Order Servomechanism

If the input $\theta_i(t)$ is a step displacement and the output $\theta_0(t)$ is determined for various values of the damping ratio, the set of transient responses illustrated in Fig. 13 results. If $\theta_i(t)$ is made a sinusoidal function

$$\theta_i(t) = A \sin \omega t$$

and the amplitude response of the output $\theta_0(t)$ is determined, the set of curves in Figs. 14 and 15 is obtained. Comparison of the transient and frequency responses reveals a number of points of correspondence: (*a*) The frequency at which the transient response oscillates (the natural frequency) is approximately the same as the frequency at which the amplitude response has a peak (the resonant frequency); (*b*) as the damping ratio is reduced the transient response becomes more oscillatory, and the peak in the amplitude response is magnified; (*c*) when the damping ratio is made larger than unity the transient response becomes sluggish and the amplitude response falls off rapidly without a peak.

It is frequently convenient to combine the information contained in the amplitude-response curve and in the phase-response curve of a system by a single graph. This can be accomplished by remembering that the amplitude ratio and the phase angle are

quantities defining a vector which relates the output and input. As the frequency of the input is varied this vector varies in phase and magnitude and the amplitude- and phase-response curves present the information on the manner in which these two properties of the vector change with frequency. The same information can be provided in an alternative way by plotting on polar co-ordinate paper the path followed by the tip of the vector as the frequency varies over the band of interest. If various points of the curve are labeled with the frequency to which they correspond one curve will supply the information contained in

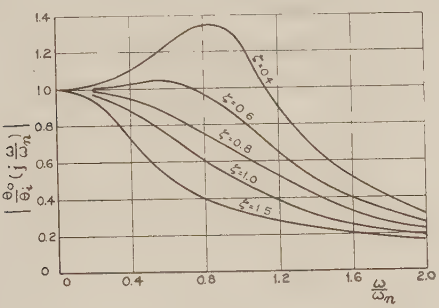

Fig. 14 Amplitude-Response Curves of Second-Order Servomechanism

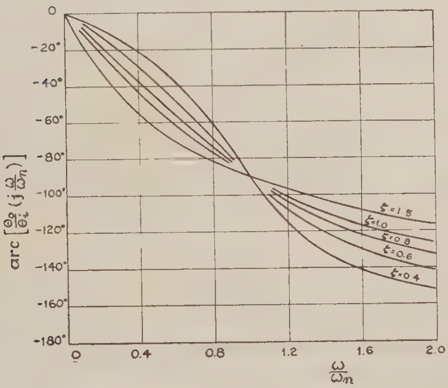

Fig. 15 Phase-Response Curves of Second-Order System

two curves when the amplitude and phase response are plotted separately. This graphical presentation is known as the locus of the frequency-response characteristic. It is illustrated in Fig. 16 which was drawn for the same second-order system to which the curves in Figs. 14 and 15 apply. The principal advantage of presenting information in this fashion lies in the means it provides for visualizing the frequency response and in the fact that it emphasizes the very important relationship that always exists between the amplitude and phase responses of a system.

14 Servomechanism Transfer Function

It is clear from the block diagram in Fig. 11 that a single function completely defines the performance of a servomechanism in which the feedback link contains no frequency-dependent elements. The defining function is the relationship between the servo output θ_0 and the error ϵ. If this relation is known in operational, sinusoidal, or time-response forms, the performance of the system is completely defined for all conditions that may be imposed upon it. This function, relating the servomechanism output to its error, has been termed the "transfer function" of the

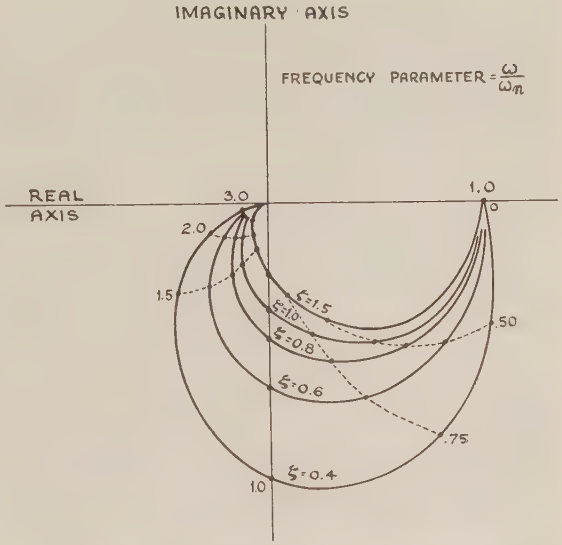

Fig. 16 Locus of Frequency-Response Characteristic of Second-Order System

servomechanism. When the sinusoidal or frequency-response form of the transfer function is studied it becomes a powerful analysis and synthesis tool. The transfer function may be derived from a known frequency-response characteristic of the servosystem, it may be measured directly, or if system constants are known, it may be calculated directly.

In terms of the nomenclature previously established in this paper the operational form of the transfer function is written $\frac{\theta_0}{\epsilon}(p)$. The sinusoidal form of the transfer function is obtained by replacing the operator p by $j\omega$, giving $\frac{\theta_0}{\epsilon}(j\omega)$. This function is a vector quantity with an amplitude and a phase characteristic just as the ratio $\frac{\theta_0}{\theta_i}(j\omega)$ is a vector quantity.

The transfer function of a servo system is always the product of two parts, one that is invariant with frequency and a second that is frequency-dependent. The fact that these two components exist is emphasized by writing the transfer function in the following form

$$\frac{\theta_0}{\epsilon}(j\omega) = KG(j\omega) \qquad [61]$$

The term K represents that part of the transfer function which is invariant with frequency. This portion is known as the gain or the sensitivity factor and is a function of amplifier gain, gear ratios, etc. The second part of the transfer function is denoted by $G(j\omega)$ and represents the portion of the transfer function which changes with frequency.

The frequency response of the servomechanism is connected with the transfer function by the following vector equation

$$\frac{\theta_0}{\theta_i}(j\omega) = \frac{KG(j\omega)}{1 + KG(j\omega)} \qquad [62]$$

The transfer function of a system is calculated by straightforward circuit-analysis techniques, or by determining the differential equation relating the output to the error and replacing $\frac{d}{dt}$ by $j\omega$.

15 The Transfer-Function Locus

The transfer function can be studied by means of its frequency characteristics just as other functions have been so studied. The amplitude- and phase-response curves of the transfer function can be drawn and these curves completely define the characteristics of the transfer function of the servomechanism and therefore completely define the system itself. Just as the phase- and amplitude-response curves were combined into a single polar plot with frequency as a parameter, so can the frequency- and phase-response curves of the transfer function be combined. This parametric polar plot of the transfer function has been called the "transfer-function locus," or simply the transfer locus of the servomechanism. The transfer locus completely defines the characteristics of the servo system. A study of its nature provides an effective method for the synthesis of servomechanisms intended for particular applications and a useful general guide to the adjustment of servomechanism parameters in order to secure optimum performance.

The reason for the effectiveness of employing the transfer function $KG(j\omega)$ as a means of analysis is explained as follows:

If it is desired to analyze the response of a servo and design compensation circuits for improving its performance, the function $\frac{\theta_0}{\theta_i}(j\omega)$ is awkward to work with directly. The reason for this arises from the complex nature of the relation between $\frac{\theta_0}{\theta_i}(j\omega)$ and the system parameters. On the other hand, it has been shown that the performance of the servo is completely determined once the transfer function $KG(j\omega)$ is known. A much simpler relation generally exists between the system parameters and the transfer function so that it is comparatively easy to synthesize a controller once the required form of the transfer function is known. The system design is applied to choosing, altering, and improving the servomotor or servo controller, the characteristics of which directly affect the transfer function $KG(j\omega)$.

Design criteria expressed in terms of restrictions upon the transfer function are therefore most easily translated into physical design. However, the final decision as to the quality of the performance of a particular servo is made from a knowledge of the character of its output function, and it is necessary therefore to translate restrictions upon the output and function into restrictions upon the transfer function. The situation is summarized as follows:

It is necessary to know the phase and magnitude of $\frac{\theta_0}{\theta_i}(j\omega)$ in order to decide if the servo is satisfactory. In synthesizing a servo it is easier to work with the transfer function $KG(j\omega)$. By correlating the transfer-function characteristics with the properties of the system frequency response, an effective design procedure can be developed. The correlation of these two functions is most easily effected graphically, as described in the following:

If a parametric frequency plot of the transfer function $KG(j\omega)$ is available, the magnitude and phase of the function $\frac{\theta_0}{\theta_i}(j\omega)$ may be found by graphical calculation. The function $\frac{\theta_0}{\theta_i}(j\omega)$ has been related to the transfer function by Equation [62].

A plot of a typical transfer function $KG(j\omega)$ is illustrated in Fig. 17. Suppose it is desired to calculate $\frac{\theta_0}{\theta_i}(j\omega_c)$ for a particular frequency ω_c, with only the transfer locus available. The transfer function at ω_c, $KG(j\omega_c)$, is represented by the vector $\overline{oc}$ while the vector $\overline{ac}$ represents the term $[1 + KG(j\omega_c)]$, since the point a is located at $(-1 + j0)$. Therefore the magnitude of $\frac{\theta_0}{\theta_i}(j\omega_c)$ is given by

$$\left|\frac{\theta_0}{\theta_i}(j\omega_c)\right| = \frac{|KG(j\omega_c)|}{|1 + KG(j\omega_c)|} = \frac{|\overline{oc}|}{|\overline{ac}|} \qquad [63]$$

while the phase of $\frac{\theta_0}{\theta_i}(j\omega)$ is given by

$$\text{arc}\left[\frac{\theta_0}{\theta_i}(j\omega_c)\right] = \text{arc}\,(oca) \qquad [64]$$

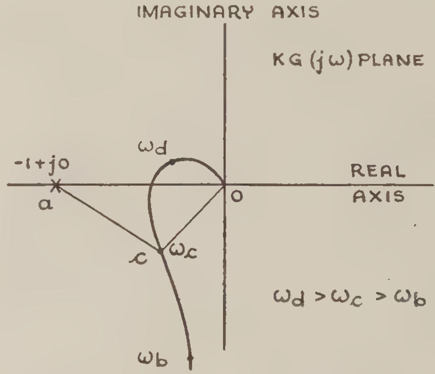

Fig. 17 Graphical Determination of $\frac{\theta_0}{\theta_i}(j\omega)$ From Transfer Locus

The angle, arc (oca), is negative. Thus the magnitude of $\frac{\theta_0}{\theta_i}(j\omega_c)$ is equal to the ratio of the magnitudes of the vectors $\overline{oc}$ and $\overline{ac}$ and the phase of $\frac{\theta_0}{\theta_i}(j\omega_c)$ is equal to the angle between these two vectors.

Equations [62] and [63] permit ready visualization or calculation of the magnitude and phase of $\frac{\theta_0}{\theta_i}(j\omega)$. At small frequencies such as ω_b (see Fig. 17), both vectors $\overline{oc}$ and $\overline{ac}$ are large and approximately equal, and their ratio is approximately unity. The angle between the two vectors, the phase of $\frac{\theta_0}{\theta_i}(j\omega)$, is small at this frequency. As the frequency increases the angle between the two vectors increases and their lengths become smaller so that differences in their lengths cause the ratio $\frac{\overline{oc}}{\overline{ac}}$ to depart from unity. Whether the ratio $\frac{\overline{oc}}{\overline{ac}}$ (the magnitude of $\frac{\theta_0}{\theta_i}[j\omega]$) increases or decreases as the frequency increases depends upon the shape of the curve relative to the origin and the point $(-1 + j0)$. A continuation of this reasoning for the remainder of the frequency range permits the general shape of the phase and magnitude of the servo output to be completely determined. If desirable, the phase and magnitude curves can be determined from the transfer locus with accuracy and ease by using a protractor and divider and measuring the angles and lengths directly from the graph.

Correlation between other servomechanism characteristics and the shape and form of the transfer locus are described in the following sections.

16 Absolute Stability Criterion

The primary requirement that almost every servomechanism

must satisfy is that of stability. Although a servo system must be more than barely stable to be satisfactory, a stability criterion of one type or another is generally the first test applied to proposed servomechanism design. Several criteria exist; however, the one described here was developed primarily for application to feedback amplifiers. It is at once apparent to those familiar with feedback-amplifier theory that the transfer locus of a servomechanism is analogous to the Nyquist diagram of a feedback amplifier. The term Nyquist diagram has been given to this type of plot for a feedback amplifier because of a very useful criterion developed by Nyquist (8) for determining the stability of a feedback amplifier. This criterion may be applied equally well to the transfer locus in order to determine from its shape and position whether or not the servomechanism for which it is drawn is stable. To apply the Nyquist stability criterion to servomechanisms, the following procedure is employed: (*a*) The transfer locus [$KG(j\omega)$ plotted in polar form] is drawn for all frequencies from zero to infinity; (*b*) the conjugate of the transfer locus is drawn. The conjugate of a curve is the mirror image of the original curve about the real axis; (*c*) if the curves so formed enclose the point $(-1 + j0)$, the system is unstable. If the curves do not enclose this point, the system is stable. The application of this criterion is illustrated in Fig. 18.

The foregoing criterion applies to curves of closed form; that is, it applies to transfer loci of such character that the loci and their conjugates join at zero and at infinite frequency. Actually the transfer loci of most servomechanisms are of the open form and some extension is required in order to apply the stability criteria to these forms of transfer loci. The open form of the transfer locus can be changed into the closed form by connecting the curve and its conjugate at the zero-frequency point by means of a circle of infinite radius. The connection should always be made in such a way that no phase discontinuity occurs along the path of the curve.

This is illustrated in Fig. 19 in which are plotted the transfer loci of two common types of servomechanisms, both of which are stable.

17 Transfer Loci for Various Types of Steady-State Performance

The performance of a servomechanism under steady-state conditions is always of great importance. If the servomechanism is primarily a positional device it is desirable that the servomechanism take up various positions without requiring an error to maintain it in that position. Similarly it is frequently necessary for the servomechanism to follow an input of constant velocity, that is, one in which $\theta_i(t) = kt$. In this case it is desirable for the servomechanism to follow various velocities as required without the necessity of a system error to maintain that velocity. Servomechanisms that satisfy the first condition frequently are termed zero-displacement-error servomechanisms and servos that meet the second condition similarly are called zero-velocity-error servomechanisms. It can be readily shown that if the transfer locus of a servomechanism approaches infinity along the negative imaginary axis, the servo will have zero-displacement error. Similarly if the transfer locus of a servomechanism approaches infinity along the negative real axis that servo will have zero-velocity error. The zero-velocity-error servo will, of course, have zero-displacement error also. In Fig. 19 is illustrated the transfer loci of a zero-velocity-error system and of a zero-displacement–error system.

This concept can be extended to servo systems that will follow a constant input acceleration without steady-state error, and so forth.

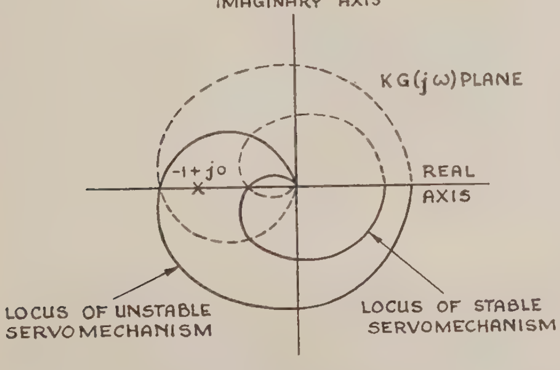

Fig. 18 Application of Nyquist Stability Criterion to Servomechanisms With Positional Error

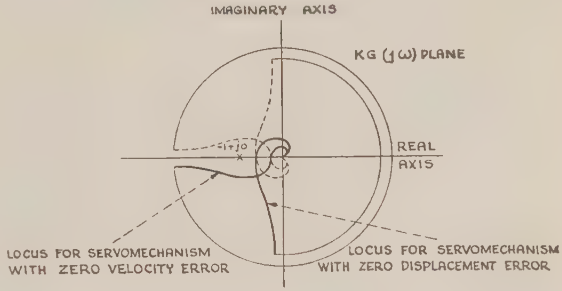

Fig. 19 Extension of Nyquist Stability Criterion to Zero-Displacement-Error and Zero-Velocity-Error Servomechanisms

18 Determination of the Gain Factor (K)

The particular servo parameter most easily adjusted is, perhaps, the gain factor K, which is the frequency invariant portion of the transfer function, $KG(j\omega)$. If the servocontroller is an electronic amplifier, the gain may be fixed, in general, by adjusting a voltage divider controlling the gain of the amplifier. The gain factor of systems incorporating controllers other than electronic amplifiers may be less easily adjusted, but the procedure in most cases is still relatively simple. Since the gain is easily adjusted and since its setting is so important in determining the characteristics of a servomechanism, it is important to develop a technique of gain adjustment that yields optimum results in servo performance.

The effects of increasing the gain or sensitivity of the servomechanism are (*a*) the velocity error of the system is reduced if the servomechanism is of the zero-displacement-error type; (*b*) errors caused by restraining torques on the servo output are reduced; (*c*) errors caused by mechanical misalignment in the servomotor or controller are reduced; (*d*) the imaginary components of the complex roots of the system (the natural frequency or frequencies of the system) are increased in most cases; (*e*) the magnitudes of the real roots of the system are increased in most cases; and (*f*) the real parts of the complex roots of the system (the damping constants) in general are decreased. The first three of these effects reduce the system steady-state error; the next two increase the speed of response of the system, and the last reduces the speed of response of the system in that the time required for a transient oscillation to damp out is increased. A general rule that can be deduced from the factors given is that

the servomechanism sensitivity should be as high as is compatible with proper servo stability.

Any physical closed-cycle system can be made unstable if the sensitivity is sufficiently increased. This is evident from the transfer locus of a physical servomechanism since such a locus always crosses the real axis and therefore as the sensitivity or gain factor K is increased, the locus will enclose the $(-1 + jO)$ point at some finite sensitivity and the servo will become unstable. The gain factor should always be adjusted to avoid instability.

Most applications, however, require not only that the servo be stable but that its degree of stability be satisfactory. The degree of stability determines the damping of the oscillatory components of the servo transient response and in general the gain factor should be so selected that these response components are well damped. When the oscillatory components are insufficiently damped the transient response requires an excessive time to reach its final value and exhibits excessive overshoot. In addition, the amplitude response possesses excessively high peaks. The effect on the transient response is illustrated in Fig. 13 which shows that as the damping ratio is decreased the oscillatory nature of the system is more pronounced. The effect on the amplitude response is indicated in Fig. 14 which shows that as the damping ratio is decreased the magnitude of the peak in the response is augmented.

When a servomechanism is designed on the transient basis the degree of stability is controlled by requiring the effective damping ratio to be of the order of 0.5. When a servomechanism is designed on the frequency-response basis it has been found that an equally satisfactory criterion is to limit the magnitude of peaks in the amplitude response to approximately $1^1/_3$. Neither requirement is based upon exact mathematical criteria; both have been found to give good results in almost every application.

The determination of the gain factor K, that will limit the maximum value of the amplitude response to a prescribed value and thus provide adequate damping in the system, is easily carried out graphically through the use of the transfer locus of the system. If the ratio $\left|\frac{\theta_0}{\theta_i}(j\omega)\right|$ is denoted as M for a particular frequency, curves of constant M can be drawn in the $KG(j\omega)$ plane. These curves turn out to be circles whose centers and radii are easily determined. A set of these circles is illustrated in Fig. 20 together with the transfer locus of a typical servomechanism. The significance of these curves lies in the fact that wherever the transfer locus crosses one of these circles it indicates that at the frequency for which the intersection occurs the value of $\left|\frac{\theta_0}{\theta_i}(j\omega)\right|$ is equal to the M corresponding to the intersected circle. Thus in Fig. 20 $\left|\frac{\theta_0}{\theta_i}(j\omega)\right|$ for the system whose transfer locus is denoted by $K - 1$ will have a value of 1.1 at 1 cycle per sec, 1.5 at 2 cycles per sec, 0.75 at 3 cycles per sec, etc. A value of M can generally be found so that the circle corresponding to this M value is tangent to the transfer locus at some point. A point of tangency indicates that the function $\left|\frac{\theta_0}{\theta_i}(j\omega)\right|$ has a maximum or a minimum at that point. Thus in Fig. 20 the transfer locus drawn for $K = 1$ is tangent to the $M = 1.5$ circle, indicating that the output function has a maximum of 1.5 at 2 cycles per sec.

Also drawn in Fig. 20 are the transfer loci for the same servomechanism with different values of gain factors. It is evident that the maximum value of the output function increases as the gain factor is increased. The proper degree of stability is determined by sc choosing the gain factor that the transfer locus corresponding to this gain factor is tangent to the circle drawn for the predetermined maximum value of M.

19 Basic-Design Procedure

Since the transfer-function approach is perhaps most useful in the design and synthesis of servomechanisms, the principal steps in the design procedure employing the frequency-response approach are summarized as follows:

(a) Determine the transfer function $KG(j\omega)$ for the first approximation to the complete servomechanism. This requires the determination of the amplitude and phase characteristics of $KG(j\omega)$.

(b) Plot this transfer function in the form of a transfer locus using the specific values determined from (a).

(c) Decide on the degree of stability required in terms of the M ratio discussed in section 18 and determine the gain factor that will produce tangency between the transfer locus and the circle drawn for the maximum permissible value of M. The gain factor can then be used to determine actual sensitivities in the servosystem. Determine the frequency at which the maximum value of $\left|\frac{\theta_0}{\theta_i}(j\omega)\right|$ occurs.

(d) From a knowledge of the permissible sensitivity, the frequency at which the function $\left|\frac{\theta_0}{\theta_i}(j\omega)\right|$ is maximum, and the zero-frequency behavior of the transfer locus, answers can be obtained to the following questions:

1 Is the servomechanism of the type (zero-displacement-error servo, zero-velocity-error servo) suitable for the particular application?

2 Can the gain factor be adjusted to secure adequate damping?

3 Is the sensitivity permitted by adequate damping sufficiently high to minimize the effect of nonlinear factors such as sticky valves, dry friction on the output member, etc., and linear factors such as velocity and acceleration error, etc.?

4 Is the natural or resonant frequency sufficiently high to provide the speed of response required by the application?

(e) If the answer to any of the foregoing questions is negative remedial action must be taken. Readjustment of certain of the parameters or minor changes in design may be sufficient. Otherwise major design changes must be made or corrective devices incorporated in the system. These corrective devices can be designed: (a) To improve the transient response; (b) increase the sensitivity permitted by adequate stability; or (c) change the basic type (zero-displacement error, zero-velocity error) of the servo. If the corrective element is introduced as an element cascaded with the controller in such a way that no mutual reaction with other elements occurs, the new transfer function is the product of the old transfer function and the transfer function of the corrective element. The new transfer locus can be formed graphically by multiplying amplitudes and adding phases for a particular frequency. If the corrective element is inserted in the system in a different manner straightforward circuit-analysis techniques can be applied to the determination of the transfer function.

20 Summary

Two approaches to the mathematical analysis of servomechanisms have been pointed out in this paper. It has been demonstrated that, in general, a broad understanding of servomechanisms could be obtained by an understanding of both approaches, and in particular, that valuable performance and design data could be obtained. It has been shown that the transient approach

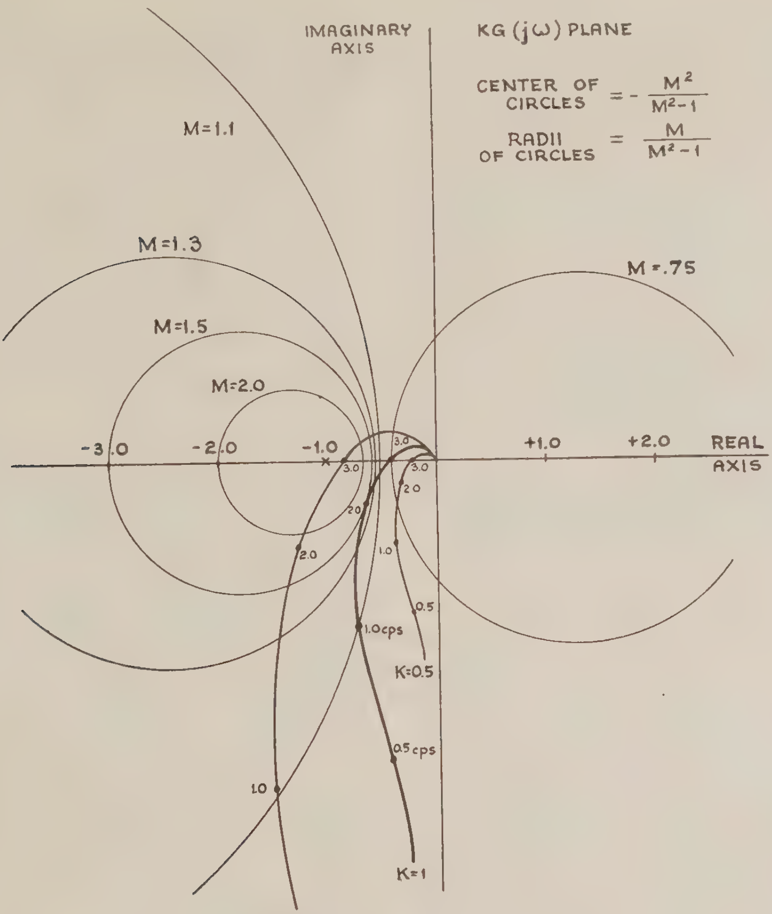

FIG. 20 GRAPHICAL DETERMINATION OF GAIN FACTOR OF TRANSFER LOCUS

is particularly valuable when the exact response to known inputs is required, and in the analysis of simpler servo systems. It has been further shown that the frequency-response approach is indispensable when the analysis and synthesis of complex servo systems is required.

ACKNOWLEDGMENT

The authors gratefully acknowledge the co-operation and assistance of their colleagues at the Massachusetts Institute of Technology. Particular thanks are due to Mr. H. T. Marcy and Mr. G. J. Schwartz for their many valuable suggestions, and to Mr. D. P. Campbell for his contributions to the transient-analysis approach.

Discussion

C. Concordia.[6] The writer is greatly interested in the steady-state method of analysis of control systems described in this paper and would like to comment on what he considers its scope in relation to other aspects of the control problem.

If one starts from scratch and constructs a control system for a particular job, one's first task is to make sure that the system is stable. For this purpose it seems best to find regions of stable operation in terms of those parameters which are within our control by the application of Routh's stability criteria to the characteristic determinant of the system. Such a study gives information over a great range of system parameters very quickly, without the necessity of studying any one system in detail.

Following such a study, one becomes concerned with the response of the system. The most direct method might appear to be to compute directly the transient response to the various disturbances which are of interest. However, for the reasons discussed by the authors, this sort of calculation does not tell immediately what to do in order to improve performance. Thus it is convenient to devise on a semiempirical basis criteria of probable transient performance in terms of steady-state performance and to make steady-state studies of the system as they have described.

However, even after this is done, one may still wish to make sure that performance will be satisfactory by a direct study of the transient performance. This is especially true in those cases where the system may be subjected to a variety of different kinds of disturbances. An example of this is an airplane-engine turbo-supercharger regulator, which may be subjected to disturbances of the pressure-boost setting, the engine-speed setting, or the throttle setting. It will be apparent to those familiar with control-system performance that the optimum stabilizer design for one type of disturbance will not be the same as that for the others, so that the over-all optimum must be a matter of engineering judgment rather than of mathematical criteria.

For the purpose of making such studies of transient performance we have found it convenient to use the differential analyzer. Of course, once a problem is set up on the differential analyzer it is a simple matter to change parameters and run off the resulting transient-response curve, and in fact in many cases this has been so attractive that we have shortcircuited completely the intermediate steady-state analysis method.

A further reason for this is that in many cases, as the refinement of design proceeds, one becomes primarily interested in studying more and more the effects of those nonlinear elements such as friction, backlash, saturation, etc., that are left out of the linear analysis which has been described. A further related factor is that a linear analysis becomes more nearly valid as the control means become better. In many cases very limited control means may be available, and these may be essentially off-on or some other kind of contact control. In these cases it is almost necessary to determine the transient response directly if a good idea of the quality of actual performance is to be had.

[6] Engineer, General Electric Company, Schenectady, N. Y. Mem. A.S.M.E.

L. A. MacColl.[7] It is shown in the paper that the function $KG\ (i\omega)$ plays a dominant role in the theory of the particular servomechanism which is under consideration. Perhaps it will be well to point out explicitly that this function, suitably generalized, is fundamental in the theory of any single-loop servomechanism, and to indicate how the generalized function can be determined experimentally.

Let us consider a general single-loop servomechanism, in which we have a "forward circuit," consisting of certain components $C_1, C_2, \ldots, C_l$ connected in tandem, and a "feedback circuit," consisting of certain components $C_{l+1}, C_{l+2}, \ldots, C_{l+m}$ connected in tandem.

The typical component C_n is characterized by a complex-valued function $Y_n\ (i\omega)$, having the following significance: In the steady state, in which all of the signals in the system are varying sinusoidally with time with the radian frequency ω, the absolute value of $Y_n\ (i\omega)$ is the ratio of the amplitude of the signal at the output of C_n to the amplitude of the signal at the input of C_n, and the angle of $Y_n\ (i\omega)$ is the phase difference between these two signals.

Now it is easily shown, by reasoning like that employed in the paper, that the function

$$Y(i\omega) = Y_1(i\omega)Y_2(i\omega)\ldots Y_l(i\omega)\ Y_{l+1}(i\omega)Y_{l+2}(i\omega)\ldots Y_{l+m}(i\omega)$$

plays the role in the theory of the present system that the function $KG\ (i\omega)$ plays in the theory of the system discussed in the paper.

Let us consider the physical significance of $Y\ (i\omega)$. Suppose that we open the feedback loop between any two consecutive components, say the components C_n and C_{n+1}, adding the proper terminations, if necessary, so that the impedance relations within the system will not be disturbed. Then let us impose a known sinusoidal signal at the input of C_{n+1}, and let us measure the amplitude and phase of the resulting signal at the output of C_n. It is readily seen that the ratio of the amplitude of the signal at the output of C_n to the amplitude of the signal at the input of C_{n+1} is the absolute value of $Y\ (i\omega)$, and that the phase difference of the two signals is the angle of $Y\ (i\omega)$. On this account $Y\ (i\omega)$ is commonly called the "loop transmission ratio of the servomechanism."

We note that where we open the feedback loop, whether between C_1 and C_2, or between C_2 and C_3, or elsewhere, is indifferent in principle. However, as far as experimental technique is concerned, it may not be practically indifferent. In many cases the physical nature of the signals changes from point to point in a servomechanism. At one point the signal may be the angular position of a shaft, at another point it may be an electromotive force, and at a third point it may be the pressure of a fluid. In

[7] Bell Telephone Laboratories, Inc., Murray Hill, N. J.

such a case it may well be that we can perform the measurements just described more accurately and conveniently at one point in the loop than at another. We should, of course, select the point at which we open the loop, and perform the measurements accordingly.

Referring to the significance and use of the Nyquist diagram: Suppose that we have a servomechanism with a Nyquist diagram which encloses the critical point (—1, 0), so that the system is unstable, or which, while it does not actually enclose the critical point, passes near to that point, so that the system is barely stable. In either case, we have to modify the system in some way, in order to make its performance satisfactory.

One rather obvious thing we may do is simply to vary the value of some one constant parameter, seeking a particular value which gives a satisfactory performance. This procedure, which is discussed at length in the paper, may be entirely satisfactory in many cases. However, it is evident that this procedure is quite restricted, and it is to be expected that we can often achieve more satisfactory results in other ways. Here the Nyquist diagram performs a great service; for it reveals a great variety of means for obtaining a satisfactory system, many of which are not suggested at all by the older methods.

In so far as satisfactory stability of a servomechanism is concerned, all that is necessary is that the curve of the Nyquist diagram shall neither enclose the critical point (—1, 0) nor pass too near to that point. In order to achieve a curve which is satisfactory in this sense, we can confine ourselves to varying element values, if that is sufficient, or we can insert additional frequency-selective elements in the system, so as to alter the very form of the curve in a drastic manner. The possibilities of the latter sort are particularly valuable when we are dealing with complicated systems subject to stringent requirements.

Ed S. Smith.[8] The authors deserve the thanks of mechanical engineers for the release of this material as soon as the wartime restrictions lifted. It is high time for this M.I.T. group of electrical engineers to claim due credit for its excellent work and real contributions to the war effort. The writer is glad to acknowledge here his professional and personal indebtedness to Bush, Hazen, Gardner, Draper, Brown, Harris, Hall, Campbell, Kochenberger, Taplin, Philbrick, and Ahrendt, to name a representative number of its more active contributors to the art. At the same time, it must be remembered that the pioneering in servomechanisms has been shared by another group of electrical engineers at the Bell Telephone Laboratories: Nyquist, Bode, Black, Ferrell, Dietzold, MacColl, and Barnes whose work with Gardner at M.I.T. is but one tie of many between these two groups.

As a mechanical engineer, the writer's primary interest is to see how these electrical-engineering techniques may be best made available to other engineers, for use in control generally. For this "transmission problem" it is good that such an experienced and co-operative teacher as Brown heads the A.I.E.E. activity in this field. For the sake of continuity, it is hoped by the writer, as the current chairman of the A.S.M.E. Instruments and Regulators Division, that such activity will be most intimately tied in with the work of this division which sponsored this paper. This division in the past has followed control theory as exemplified by papers by Ivanoff, Minorsky, and division members including Fairchild, Grebe, Mason, Sperry, and the present writer to mention a token few. The following comments are purely individual:

It might offhand seem that servomechanisms should form ideal examples of control for mechanical engineers since the familiar elements are the inertia of a mass, the damping of a dashpot, and the proportional effect of a spring. However, from the standpoint of the process-control engineer, these happen to overstress inertial and oscillatory effects. Also mechanical analogs are a bit more farfetched than the hydraulic which has the advantage of more closely corresponding with the electrical systems in which these electrical engineers really think.

Ideally, each actual system should be directly followed in setting up the mathematical formulation which would then be used in a pure form in obtaining results. But this procedure would deprive the creative engineer of the stimulus derived from working in the medium of his experience. Since so much of the literature will be on electrical-engineering techniques, it appears that each active control engineer should become adept in their use.

The experts in the servomechanism and control fields are unfortunately not exceptions to the rule that the experts in an art always ball up the terminology and notation until they can be followed only by a like expert. To a control engineer, if a regulated temperature is too high, the error would be positive and taken as $(T_{\text{actual}} - T_{\text{set}})$. To a "servomechanist," it would seem that the temperature setting T_i was not being followed by the actual temperature T_0 and that the error would be $(T_i - T_0)$. For another example; probably the most important factor in control is the variable "load" which often affects a most inconvenient part of the plant with effects echoing around and around the system, whereas too often the servomechanist either entirely neglects the load change or shrugs it off as mere "hash" or "noise," a mere random impulse without the dignity of identity.

Again, the "controlleer" is charged with habitually over-simplifying analyses, using an occasional integral or appropriate derivative in visualizing the ills and cures of regulated systems reference (16), whereas the servomechanist seems to tend to stick to the more readily available means for obtaining a typical $(1 + Tp)$ term without, in so far as the present writer can see now that the veil of wartime secrecy has been pierced, creating any essentially new form of regulator. At least the controlleer can directly express a ratio of effect to its cause and the lag without becoming involved in the width of a hypothetical frequency-transmission band and in such an acoustical abstraction as "decibels per octave."[9] The point appears to be that the tools of the different arts have different advantages to those who are familiar with their use.

Finally, on this point, the controlleer's need is for an approach which will enable him most flexibly to solve a wide variety of control problems, whereas to the servomechanist, the temptation appears to be irresistibly strong to go overboard on overspecialized treatments, e.g., the nondimensional approach, for the sake of greater efficiency in his special field at the expense of widest utility, with the result that anyone not working steadily in that field will usually save considerable time and be more certain of the correctness of his results if he starts from scratch and sticks to the closest relation between the physical phenomena and the mathematics.

A noteworthy exception to this is that grand tool, the Nyquist method of testing stability. This is essentially so simple that it is difficult for even experts to confuse although they bring in the "conjugate complex," and the idea of "negative frequencies." It may be well here to restate the Nyquist criterion following Harris' rule: A regulated system is unstable only if, 1 the sensitivity (effect/cause) exceeds unity at a lag of 180 deg, and 2, the lag there increases with increasing frequency at the least value of sensitivity which is greater than unity. Of course in

[8] Eclipse-Pioneer Division, Bendix Aviation Corporation, Teterboro, N. J. Mem. A.S.M.E.

[9] "The Servo Problem as a Transmission Problem," by E. B. Ferrell, Proceedings of the Institute of Radio Engineers, vol. 33, November, 1945, pp. 763–766.

any actual system the sensitivity finally must decrease to zero with increasing frequency.

It may lend confidence in this method to note that this was independently approached from purely practical considerations. The writer in 1936 remarked[10] that the time lags in a regulated system were best observed by taking effects in the same direction as their causes, which amounts to dropping the 180 deg for the control relation, as is now conventional. Ivanoff in 1938 (U. S. patent 2,268,285) showed familiarity with the requirement that the lag be 180 deg for steady hunting. And Fairchild in 1940 (Temperature Symposium) noted that the further requirement for steady hunting was that the over-all sensitivity be unity. (Incidentally, as Le Corbeiller noted, to tend to sustain oscillations reliably at substantially a definite amplitude, there must be such a nonlinearity that, upon a decrease of amplitude, the over-all sensitivity or "gain" increases. All other material in this discussion is limited to linear systems.)

In evaluating the advances claimed in the paper: Apparently Harris (21) advanced the Nyquist technique mainly by using the grids of the paper's Fig. 20 to show the sensitivity, with maximum and minimum values of (θ_0/θ_i) where the circles are tangent to the Nyquist loci of the vectors. The advance of Hall (13) is mainly in the systematic correlation of the circuits and networks with their control relationships; and Taplin's pioneering use of $(1 + gh)$ in the denominator, while limited to very simple systems such as elementary servomechanisms without multiple feedback loops, still had wide implications and represents a logical operational advance. The foregoing is an offhand effort to bring the work of these contemporaries into better focus.

It is unquestionably valuable to "block up" a system for the purpose of setting up the equations as a standard procedure, and to use a-c network techniques in obtaining the over-all sensitivity, gain, or transfer ratio, expressed by the appropriate *gh*. . . relations. This is useful both as a test for stability and as an indication of the transient performance of the system under such standard forcing functions as the impulse, step, ramp, etc., by the use of the frequency-analysis techniques, notably the Fourier, as recently advocated by Harris. In other words, the formal transient analysis may be entirely replaced by the frequency approach.

Since the paper refers to several publications of the authors' group, it may be a service to engineers attempting to use such publications to note the following: In reference (1), Draper and Bentley, in Figs. 3 and 6, 1.58 should be 1.74. In reference (10), Weiss, the cubic chart III*a* is incorrect in part, a correction having appeared only in a classified paper by one of the authors; and in reference (11), Liu, an approximation-producing assumption appears to be unstated therein which affects the accuracy of this approach in certain ranges which are still useful in control. It is hoped that any like points which later turn up in present and future papers in this field will be scrupulously cleared by publication.

Nothing of the foregoing discussion is to be construed as minimizing the value of the papers by this group. Instead, the writer has noted that the "servomechanism approach" is also of value[11] in control generally, paradoxically including self-operating regulators. The writer is happy to express his indebtedness to members of this group and their works.

It is the main purpose of the writer, as an occasional worker on control, objectively to direct the attention of other mechanical engineers to useful control tools wherever found.

Authors' Closure

The authors appreciate the comments made by Messrs. Concordia, MacColl, and Smith, particularly for their efforts to supplement the work given in the paper.

Mr. Concordia's comments on the usefulness of a Differential Analyzer to aid in the design are very pertinent though such devices are not widely available. However, as the work on similators or transient analyzers[12] for dynamical systems progresses and more of them become available their use may get widespread adoption. The one difficulty still remaining will be that of determining the parameters of the elements of the system or the various functional relationships that define the system elements. Then, of course, when these data are known a great deal can be done by steady-state sinusoidal analyses by persons not having the use of a Differential Analyzer. By skillful direction of experimental techniques during the determination of much of the basic data on the components, the work of applying the steady-state methods of analysis is considerably reduced.

Dr. MacColl's comments are very pertinent, particularly when one realizes the wide range of physical quantities encountered in any single control system and the relative ease with which certain quantities can be measured in practice and the relative status of the art of measurement of other quantities. For example, at one end of the scale one observes the simplicity and accuracy with which time-varying electrical quantities can be measured compared with the difficulties at the other end of the scale involved in measuring time-varying quantities such as acceleration, pressure, strain, fluid flow and the like.

Dr. MacColl's comments on the need to change the shape of the locus on the Nyquist diagram are appreciated for they give added emphasis to the point which, while included in the treatment under section 19 of the paper, was probably not stressed as much as it might have been.

Mr. Ed Smith's summary of the control analysis and synthesis picture as it exists today is a very timely one. Wartime emphasis on extending analytical techniques in this field were very intense. The old oft-stated gap that used to exist between the various engineering professions is rapidly narrowing as the analytical techniques of the communications engineer are explained to the mechanical engineer, and the "systems" concept is applied more and more vigorously to control problems. The integration within the professions is being stimulated by discussions between professional groups who, until a few years ago, had few common problems. Nowadays one finds a great deal of mathematics, electronics, circuit theory, electrical machinery theory, hydraulic machinery theory being interwoven into a co-ordinated systems design with corresponding benefit to that branch of the art being developed by each group. But this interweaving or integrating is occurring with harmony and a degree of co-operation between engineers of widely different background, in a very interesting way.

Conversion of Measurements of Power Output of Diesel Engines to Standard Atmospheric Conditions[1]

By MARTIN A. ELLIOTT,[2] BRUCETON, PA.

This report presents and analyzes data obtained on the effect of ambient or atmospheric conditions on the power output of three normally aspirated commercial four-stroke-cycle Diesel engines. Different ambient conditions were simulated by maintaining the desired pressure in each of two surge tanks, one connected to the intake and one connected to the exhaust of the engine. The simulated absolute pressures ranged from 20 to 30 in. of mercury. Most of the tests were made at the prevailing atmospheric temperature but a series of tests with one engine was made at an intake temperature of approximately 230 F. Analysis of the results showed that an algebraic relation could be obtained between so-called "derived indicated efficiency" and fuel:air ratio. This relation is independent of ambient conditions and is used in the development of rational procedures for correcting measurements of power output made at existing test atmospheric conditions to any arbitrarily selected standard ambient condition. Using certain of the basic relations developed, an expression was derived for computing the brake horsepower of an engine at any ambient density and rate of fuel consumption. Computed values were within 0.7 hp of values determined experimentally. The report also reviews previous work in the field and indicates the need for further work to obtain the complete solution of the problem desired by the A.S.M.E. Special Research Committee on Internal-Combustion Engines.

Introduction

In making performance tests of Diesel engines, differences in the density and moisture content of the ambient atmosphere are inevitable at different test locations and at different times in the same location. Since the power output of a Diesel engine operated at a given speed and throttle setting is affected by changes in the density of the intake air, it is desirable to develop methods for correcting the power output of an engine determined at existing ambient conditions to power output at some arbitrarily chosen standard ambient condition.

Members of this Society, who were instrumental in organizing the Special Research Committee on Internal-Combustion Engines, recognized the need for fundamental information on methods for expressing the power output of Diesel engines at standard ambient conditions, and a program of research (4)[3] was prepared outlining the work required to develop the necessary information. In formulating this program an analysis was made of performance data on Diesel engines obtained incidentally by the Bureau of Mines in studies of the effect of barometric pressure on the composition of the exhaust gases produced by Diesel engines. The tests were limited in scope in so far as engine performance is concerned since the main objective of the Bureau of Mines investigation was to determine the hazards of operating Diesel engines underground in places where the barometric pressure might be low. In spite of this, analysis of the data furnished considerable information on possible methods for correcting the power output of Diesel engines to standard ambient conditions and on the probable magnitude of the correction factors. The committee thought that it might be desirable to publish this information in a progress report discussing the general problem, analyzing the data available, and indicating the additional information required to obtain a complete solution. Accordingly the following report has been prepared:

The paper presents methods for converting measurements of power output determined at existing ambient conditions to power output at some arbitrarily selected standard ambient condition. This general procedure is commonly referred to in technical literature as correcting power output to standard ambient conditions and the multiplying factors for doing this are referred to as correction factors. This terminology is used in this paper but it is pointed out that the tests reported here were not broad enough in scope to permit the development of correction factors applicable to all engines. Because of this the somewhat more general term conversion has been used in the title to describe basic procedures developed.

Review of Previous Work

Tests on the effect of atmospheric conditions on the power output of Diesel engines are reported in the literature, but none of the previous investigations has provided a generally applicable method for correcting measurements of the power output of Diesel engines to standard ambient conditions.

The results of tests to determine the effect of humidity, temperature, and pressure on the power output of a four-cylinder, four-stroke-cycle Diesel engine were reported by Everett (5). From these tests it was concluded that, at a given speed and throttle setting, humidity did not affect power output significantly, and that both temperature and pressure affected power output but the fundamental variable was density.

Everett's work (5) and later work of Doolittle (2) furnish experimental evidence on the very minor effect of humidity when excess air is present.

The results obtained by Everett (5) on the effect of pressure on power output may not represent the effect under normal operating conditions because in his tests the pressures at the intake and

TABLE 1 DESCRIPTION OF ENGINES TESTED

Engine Type	A Four-stroke-cycle, normally aspirated	B Four-stroke-cycle, normally aspirated	C Four-stroke-cycle, normally aspirated
Number of cylinders	4	4	6
Cylinder bore, in.	$4^1/_4$	4	$4^7/_8$
Piston stroke, in.	$5^1/_2$	$4^1/_2$	6
Piston displacement, cu in.	312.1	226.2	672
Maximum rated speed, rpm	1400	2600	1800
Maximum rated bhp with all accessories except fan	44	70	150
Fuel pump	Individual pump for each cylinder; fuel delivery controlled by pump-plunger by-pass	Individual pump for each cylinder; fuel delivery controlled by pump-plunger by-pass	Single-plunger, low-pressure metering and distributing type
Type of injection valve	Single hole orifice, flat-faced valve seat	Circumferential orifice (pintle nozzle); conical valve seat	Cam-actuated plunger-type injector for each cylinder. Six spray holes in each injector
Operating pressure of injection valve discharging into air at atmospheric pressure, psi	1500	1650	...
Combustion system	Cylindrical precombustion chamber with cone-shaped ends	Spherical turbulence or air-swirl chamber	Directed spray; small air-cell in piston head
Cooling system	Positive circulation, thermostatically controlled	Positive circulation, thermostatically controlled	Positive circulation, thermostatically controlled

final exhaust were not equal. For example, the pressure at the intake ranged from 10 to 16 psia, but the pressure at the final exhaust was always atmospheric (28.79–29.15 in. of mercury). Differences between the pressure at the intake and final exhaust may cause flow into or out of the cylinder during the period of valve overlap, depending upon the relation between the two pressures. This condition is abnormal, and it is desirable therefore to maintain equal pressures at the intake and final exhaust in studies of the effect of ambient conditions on the power output of Diesel engines.

Results reported by Taylor (11) and some of the results reported by Doolittle (2) also were obtained by operating engines at reduced intake pressures and atmospheric exhaust pressure and therefore may not represent normal operation at reduced ambient pressures. Data given by Taylor (11) and Doolittle (2) on the effect of temperature apply only to the engine tested and no attempt was made to generalize the results quantitatively although qualitative generalizations were made by Taylor (11).

Dennison (1) proposed a method for comparing the performance of different Diesel engines, but this method was intended to facilitate comparison of competitive designs and is not adaptable to the development of correction factors for power output.

Moore and Collins (8) have published the results of extensive tests on the effect of atmospheric conditions on the performance of a single-cylinder Diesel engine. These tests included determination of the effect of temperature at constant pressure; the effect of pressure at constant temperature; and the effect of changing both temperature and pressure simultaneously. All of these tests were made with the pressure at the intake equal to the pressure at the final exhaust. In addition, tests were made with intake pressure greater than and less than the pressure at the final exhaust. Moore and Collins contributed considerable information but many of their tests were made at fuel : air ratios far on the rich side, a condition of little practical interest. Furthermore, their analysis of the results was not carried sufficiently far to develop the fundamental theory on the effect of atmospheric conditions on power output of Diesel engines.

In preparation for an investigation by the Bureau of Mines on the effect of atmospheric conditions on the exhaust gases produced by Diesel engines, a study was made of the published results mentioned. This study disclosed that correlation of indicated thermal efficiency with fuel : air ratio had not been examined in analyzing the results of performance tests made at different ambient conditions. Such a correlation is of interest because thermodynamic considerations show that these factors are related in the theoretical fuel : air cycle (6, 10). Furthermore, it might be expected that this fundamental relationship would be unaffected by changes in ambient conditions at least over a relatively wide range of conditions. That this was true was indicated by an analysis (3) of the data of Moore and Collins (8). Once this had been established it was possible to suggest a rational basis (3) for developing methods of correcting the power output of a Diesel engine to standard ambient conditions.

Scope of Present Report

This report includes a discussion of the results of performance tests made at different simulated ambient conditions on three different commercial, four-stroke-cycle, normally aspirated Diesel engines. Methods for analyzing the data are presented and methods for correcting power output to standard ambient conditions are developed and applied to the results of actual tests. These methods are modifications or extensions of the fundamental theory presented in a previous paper (3) by the author.

APPARATUS AND PROCEDURE

Engines Tested. The principal features of the three engines tested are summarized in Table 1. Engines B and C were directly coupled to the dynamometer. Engine A was coupled to the dynamometer through a clutch. An auxiliary cooling system was used and all engines were tested without radiator or fan. The cooling-water circulating pump was driven by the engine in all tests.

Fuel. The chemical and physical properties of the fuels used are given in Table 2. Fuel F was used in tests of engine A at 600,

1000, and 1400 rpm; fuel G in tests of engine B; and fuel F in tests of engine C.

Dynamometers. Tests of engines A and C were made using a water-cooled induction-type dynamometer rated at 200 hp from 1200 to 4000 rpm. A direct-current dynamometer rated at 45 hp from 1200 to 2500 rpm was used in tests of engine B. This latter dynamometer was used in determining friction horsepower in motoring tests of all three engines.

Equipment for Simulating Operation at Different Ambient Conditions

Operation at different ambient conditions was simulated by maintaining the desired pressure in each of two surge tanks. One of these tanks was connected to the intake of the engine and one to the exhaust (see Fig. 1). The intake surge tank was 17.5 in. diam and 84 in. in length. The exhaust surge tank was 22 in. diam and 60 in. in length.

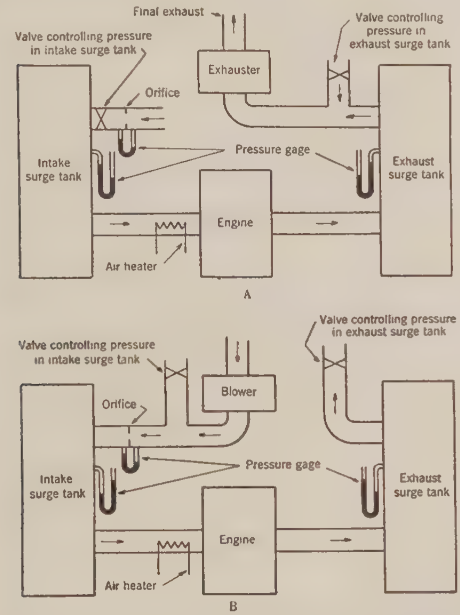

Fig. 1 Diagrammatic Sketch of Arrangements for Tests at (*A*) Ambient Pressures Less Than Prevailing Barometric Pressure and (*B*) Ambient Pressures Greater Than Prevailing Barometric Pressure

In tests at low ambient pressures (20 and 25 in. of mercury abs), the desired pressure in the intake tank was obtained by throttling a valve on the upstream side of the tank. The pressure in the exhaust surge tank was maintained the same as that in the intake surge tank by a Roots-Connersville exhauster driven in some tests by a gasoline engine and in others by an electric motor (see Fig. 1*A*).

In tests at a simulated ambient pressure of 30 in. of mercury abs, which was greater than the prevailing barometric pressure, the Roots-Connersville exhauster was used to compress air to the intake surge tank. The pressure in the exhaust surge tank was maintained at 30 in. of mercury abs by throttling a valve on the downstream side of the tank (see Fig. 1*B*).

In some tests arrangements were made for heating the intake air by manually controlled strip heaters installed in an insulated pipe 6 in. diam just upstream from the intake manifold (see Fig. 1).

Test Procedure

The desired pressures in the intake and exhaust surge tank were obtained as just outlined when the engine was operating at the speed and load selected. Final adjustments were then made in speed, load, and pressure in intake and exhaust surge tanks. The engine was then operated until equilibrium was attained and the test data recorded.

Fuel consumption was determined by an automatic fuel-weighing device which operated an electric clock and revolution counter.

Air was measured by noting the differential pressure across a thin-plate orifice upstream from the intake surge tank. The orifice and connections were installed in accordance with the published recommendations of the A.S.M.E. Special Research Committee on Fluid Meters.

In most tests with each engine the composition of the exhaust gases was determined by analysis in a Haldane apparatus. From this analysis and from the analysis of the fuel it was possible to compute the fuel:air ratio. The values obtained agreed very closely (generally within ±2 or 3 per cent) with values computed from direct measurements of fuel and air consumption.

It was not possible to motor engines connected to the induction-type dynamometer. Therefore friction-horsepower determinations were made with the engines motored by the direct-current dynamometer. In these tests the engine was warmed up

until the equilibrium lubricating-oil temperature was attained and motoring friction determined at this condition.

Test Results

The results of a typical series of tests on one of the engines are given in Table 3. To eliminate minor effects of deviations of actual speed from the nominal speed, the data on speed, fuel consumption, and horsepower are corrected to the nominal speed by assuming horsepower and fuel consumption to be directly proportional to speed. The correction is minor as the average speed was generally within ±5 rpm of the nominal speed and never exceeded ±15 rpm.

Discussion of Results

Basis for Comparing Results. The effect of ambient conditions on the power output of a Diesel engine can be determined by maintaining constant all engine operating conditions and all ambient conditions except the one whose effect is being studied. This means that comparisons of the results of tests in which a particular ambient condition is varied must be made at the same speed and throttle setting. In the Diesel engine the position of the throttle or throttle setting fixes the quantity of fuel injected at a given engine speed. If both speed and throttle setting are maintained constant, it is obvious that the quantity of fuel supplied, or in other words the fuel consumption, will be constant and will not be affected by ambient conditions. Therefore comparison of power outputs obtained at different ambient conditions must be made at the same rate of fuel consumption. This comparison can be made most conveniently by plotting brake horsepower against fuel consumption for each ambient condition studied.

Effect of Ambient Conditions on Brake Horsepower

The effect of ambient pressure on the brake horsepower of engines A, B, and C is shown in Figs. 2, 3, 4, and 5. The effect of ambient temperature (at ambient pressures of 30 and 20 in. of mercury abs) on the brake horsepower of engine B is shown in Fig. 6.

These results are presented to give a general idea of the magnitude of the effect of ambient conditions on brake horsepower and to show how the effect varies throughout the operating range of the engine tested. The following generalization may be made:

Reductions in ambient pressure or increases in ambient temperature cause significant reductions in brake horsepower at high rates of fuel consumption (higher loads). Ambient pressure or temperature does not affect brake horsepower significantly at low rates of fuel consumption (light loads).

The foregoing discussion is on the basis of the effect of the independent variables, pressure and temperature. It will be shown subsequently that density is the fundamental variable, and from the foregoing it is evident that reductions in ambient density cause reductions in brake horsepower at the higher loads but that ambient density does not affect brake horsepower significantly at light loads.

If data similar to those presented in Figs. 2 to 6, inclusive, were available for an engine it would be possible to determine correction factors graphically. However, it is desirable to develop other methods that might be more convenient and more generally applicable. In the succeeding sections the data are analyzed further to develop more rational procedures for determining correction factors for power output.

Relation Between Indicated Efficiency and Fuel : Air Ratio

The theoretical or maximum possible thermal efficiency of a given internal-combustion engine can be computed from the thermodynamic properties of the working fluid. Since these properties are related to fuel : air ratio it is evident that thermal efficiency must also be related to fuel : air ratio.

The relation between computed maximum thermal efficiency and fuel : air ratio for a limited-pressure fuel:air cycle and for an assumed compression ratio of 13.9 to 1 is shown in Fig. 7. The details of this computation have been reported previously (3) but it should be mentioned here that the limited-pressure cycle was chosen because it represents a rational criterion for comparing actual cycles of high-speed Diesel engines. The limited pressure at a given fuel : air ratio was obtained from data published by

Rothrock and Waldron (9) who made tests on an engine having a compression ratio of 13.9 : 1.

Fig. 7 shows that at fuel : air ratios, within the normal operating range of a Diesel engine, the relation between computed thermal efficiency and fuel:air ratio is linear. Since this relation is fundamental it might be expected that it would be independent of ambient conditions. It is of interest therefore to examine the relation between indicated efficiency and fuel : air ratio for the actual test results obtained at different ambient conditions.

Relation Between Fuel : Air Ratio and Indicated Efficiency Determined From Brake Horsepower and Motoring Friction

Facilities for determining indicated horsepower directly were not available in the Bureau of Mines tests. Accordingly, as an approximation, indicated horsepower was assumed to be equal to brake horsepower plus friction horsepower determined in motoring tests. It is recognized that indicated horsepower determined in this manner may be in error because of the well-known limitations (10) in determining friction horsepower in motoring tests. It should be mentioned, however, that errors in determining fric-

tion horsepower become less significant at the higher power outputs because if these errors are not too great they represent only a relatively small fraction of the indicated horsepower. For this reason trends at higher power outputs (higher fuel : air ratios) can be considered as being relatively unaffected by errors in determining friction horsepower.

For convenience, indicated efficiency will be expressed as indicated horsepower-hours per pound of fuel (ihp ÷ lb of fuel per hr). This factor does not have the same numerical value as indicated efficiency, but it is directly proportional to indicated efficiency when the heating value of the fuel is substantially constant as it was in the tests reported herein. For brevity, this factor will be referred to as "indicated efficiency" in this report. Obviously, indicated horsepower-hours per pound of fuel can be converted to indicated thermal-efficiency ratio by multiplying by the factor 2545 ÷ (heating value of fuel, Btu per lb). This conversion would of course be essential in analyzing results obtained with fuels having widely different heating values.

The relation between indicated efficiency determined as outlined and fuel : air ratio is shown in Figs. 8, 9, 10, 11, and 12. Figs. 11 and 12 which represent, respectively, results of test of engine B at 1000 rpm and engine C at 600 rpm, show that the relation is linear and independent of ambient conditions at fuel : air ratios greater than approximately 0.02 lb per lb. Figs. 8, 9, and 10 which represent, respectively, the results of tests of engine A at 600, 1000, and 1400 rpm, show that for all practical purposes the relation is independent of ambient conditions and could be approximated by a linear function at fuel : air ratios greater than approximately 0.025 lb per lb. However, at fuel : air ratios less than this the results of tests of engine A indicate that the relation is not independent of ambient conditions and is not linear.

Since theoretical considerations strongly suggest that the relation between indicated efficiency and fuel : air ratio should be unaffected by changes in ambient conditions, it is necessary to seek an explanation for deviations of test results from this presumption.

If combustion efficiency is affected by ambient conditions, it is obvious that indicated efficiency will not be independent of ambient conditions as predicted by thermodynamic considerations which assume complete combustion. In the tests reported here precise gas-analysis methods were used and carbon monoxide and aldehydes, which are products of incomplete combustion, were determined with considerable precision. The method used for carbon monoxide is sensitive to 0.01 per cent carbon monoxide and the method for aldehydes is sensitive to 5 ppm. The results of such gas analyses showed that the concentration of these products of incomplete combustion at a given fuel : air ratio were not affected significantly by changes in ambient pressure. Since there was no detectable increase in smoke production, it would seem that the apparent reductions in indicated efficiency at the low ambient pressures and low fuel : air ratios could not be accounted for on the basis of reductions in combustion efficiency.

Combustion knock was observed at the lower ambient pressures. Ignition delay probably is greater under such conditions because of the lower partial pressure of oxygen. The apparent effect of ambient conditions on indicated efficiency might have been due to the increased tendency to knock. However, if this were the case it would seem that a significant effect would have been observed at the higher fuel:air ratios where combustion knock was most severe. Since the indicated efficiency was apparently affected significantly by ambient pressure only at the lower fuel:air ratios, it is possible that combustion knock may not have been a factor. This cannot be stated definitely without further refinements in testing methods.

Indicated horsepower is only approximated when it is deter-

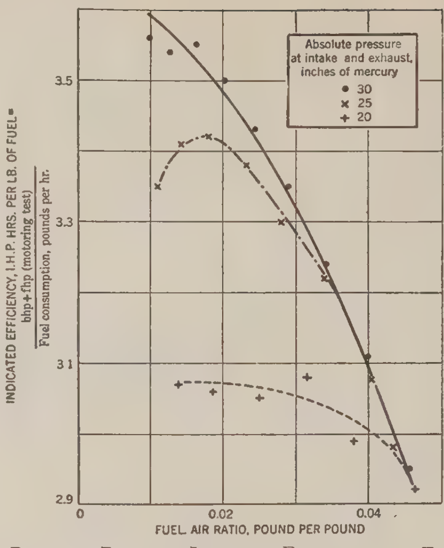

Fig. 8 Relation Between Indicated Efficiency and Fuel : Air Ratio in Tests of Engine A at 600 Rpm

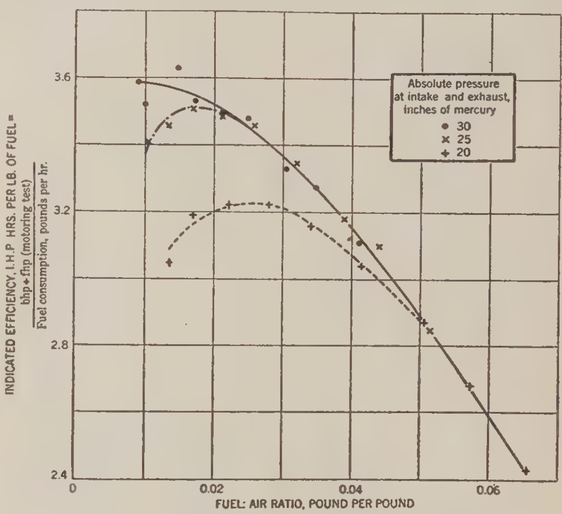

Fig. 9 Relation Between Indicated Efficiency and Fuel : Air Ratio in Tests of Engine A at 1000 Rpm

mined from measurements of brake horsepower and friction horsepower in motoring tests. As mentioned previously any inaccuracy in determining friction horsepower will be a larger proportion of the indicated horsepower at light loads (low fuel : air ratios) than at higher loads. It is possible therefore that the apparent effect of ambient pressure on indicated efficiency at the lower fuel:air ratios may have been only the result of unavoidable inaccuracies in determining friction horsepower.

It seems desirable therefore to seek a method for approximating indicated horsepower and ultimately indicated efficiency that does not involve determination of friction horsepower in a motoring test. Such a method is described in the following section.

Derived Indicated Efficiency

As mentioned previously, theoretical considerations point to a relation between indicated efficiency and fuel : air ratio that is

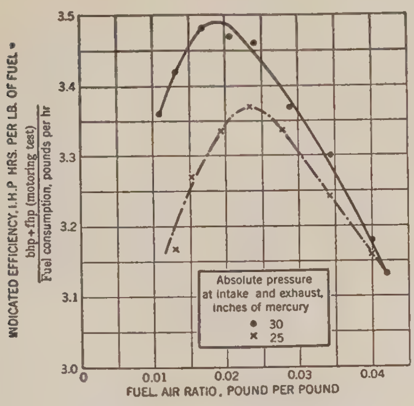

FIG. 10 RELATION BETWEEN INDICATED EFFICIENCY AND FUEL : AIR RATIO IN TESTS OF ENGINE A AT 1400 RPM

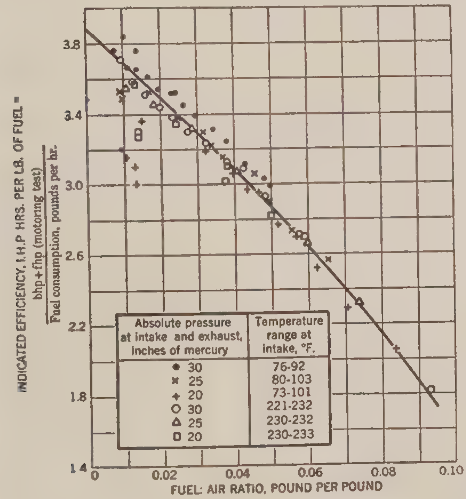

FIG. 11 RELATION BETWEEN INDICATED EFFICIENCY AND FUEL : AIR RATIO IN TESTS OF ENGINE B AT 1000 RPM

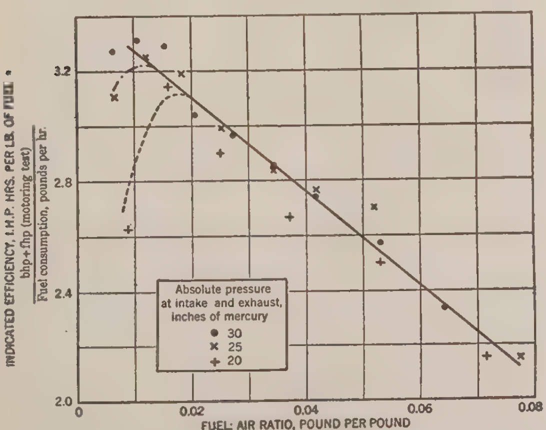

FIG. 12 RELATION BETWEEN INDICATED EFFICIENCY AND FUEL : AIR RATIO IN TESTS OF ENGINE C AT 600 RPM

independent of ambient conditions. The test results analyzed, as outlined, show that for all practical purposes this is true at the higher fuel : air ratios and that the relation is linear under these conditions. Let us assume therefore that linear relation exists in the actual engine and let the indicated efficiency determined from this relation be designated as "derived indicated efficiency." The assumed linear relation can be expressed by the following equation

$$e = e_0 - af \quad \ldots [1]$$

in which

e = derived indicated efficiency, expressed as ihp-hr per lb of fuel

f = fuel : air ratio, lb per lb

e_0 = intercept on y-axis (constant for a given engine and given engine speed)

a = slope (constant for a given engine and given engine speed)

Using the following nomenclature:

b = brake horsepower

c = derived friction horsepower (assumed constant for a given engine and given engine speed)

i = derived indicated horsepower

F = fuel consumption, lb per hr

v = volumetric efficiency (expressed as a ratio)

ρ = density of ambient atmosphere, lb per cu ft

Q = volume displaced by pistons on intake stroke, cu ft per hr

Then

$$i = eF \quad \ldots [2]$$

Substituting in Equation [2] the value of e from Equation [1], we obtain

$$i = (e_0 - af)F \quad \ldots [3]$$

Since

$$i = b + c \quad \ldots [4]$$

then from Equations [3] and [4]

$$b + c = (e_0 - af)F \quad \ldots [5]$$

If a series of tests is made at constant speed, at selected loads from no load to full load, and at a given set of ambient conditions, the value of b, F, and f will be obtained at each test condition. If we select from the data one set of values b_1, F_1, and f_1 then from Equation [5]

$$b_1 + c = (e_0 - af_1)F_1 \quad \ldots [6]$$

Subtracting Equation [6] from [5] and assuming that c is constant at a given speed and is independent of load

$$b - b_1 = e_0(F - F_1) - a(fF - f_1F_1) \quad \ldots [7]$$

Dividing Equation [7] by $(F - F_1)$ we obtain

$$\frac{b - b_1}{F - F_1} = e_0 - a\,\frac{fF - f_1F_1}{F - F_1} \quad \ldots [8]$$

Remembering that b, F, and f can be any set of values in a series of tests at constant speed but at different loads and that b_1, F_1, and f_1 are one particular set of values chosen arbitrarily, then Equation [8] shows that if $\frac{b - b_1}{F - F_1}$ is plotted against $\frac{fF - f_1F_1}{F - F_1}$, a straight line should result and it will be possible to evaluate the constants e_0 and a. It is apparent therefore that Equation [8] offers a method for determining the relation between derived indicated efficiency and fuel : air ratio by measuring only brake horsepower, fuel : air ratio, and fuel consumption in a series of tests at constant speed but at different loads.

To determine the applicability of the foregoing method of

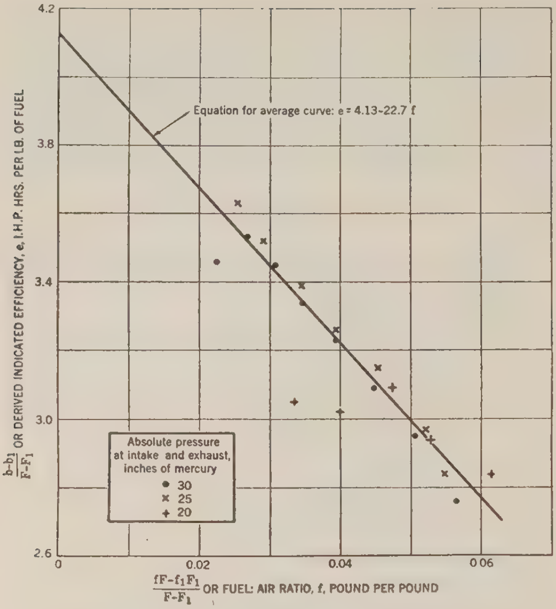

Fig. 13 Relation Between Derived Indicated Efficiency and Fuel : Air Ratio for Engine A at 600 Rpm

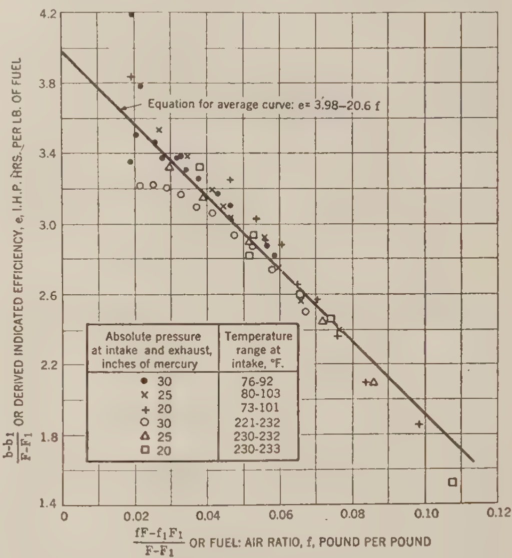

Fig. 16 Relation Between Derived Indicated Efficiency and Fuel : Air Ratio for Engine B at 1000 Rpm

analysis, the values of $\frac{b - b_1}{F - F_1}$ and $\frac{fF - f_1F_1}{F - F_1}$ were computed from the test results and are plotted in Figs. 13, 14, 15, 16, and 17. In making the computation, the test at minimum load for each constant ambient condition was arbitrarily chosen for determination of the value of b_1, F_1, and f_1.

Figs. 13, 14, and 15, respectively, represent test results obtained with engine A at 600, 1000, and 1400 rpm. It will be observed that at a given speed the results obtained at all ambient conditions can be represented with good precision by a linear relation. The same conclusion is indicated by Fig. 16 which represents data obtained in tests with engine B at 1000 rpm, and by Fig. 17 which represents data obtained in tests with engine C at 600 rpm. The average deviation from the average curve is approximately 0.08 ihp-hr per lb of fuel. Thus the average curve represents derived indicated efficiency with an average relative error that

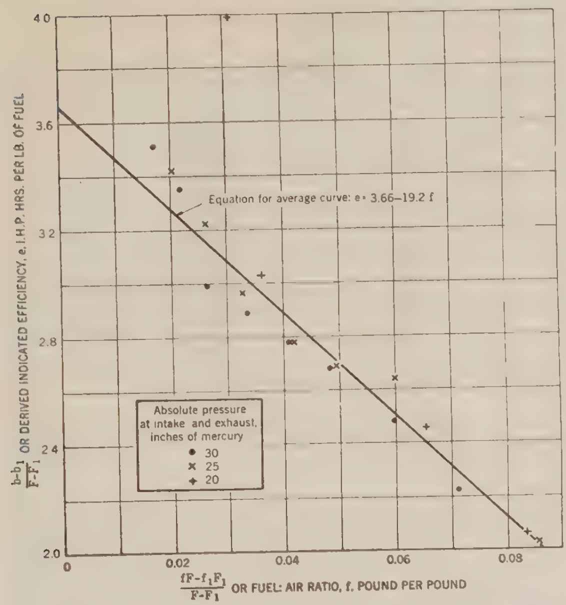

FIG. 17 RELATION BETWEEN DERIVED INDICATED EFFICIENCY AND FUEL : AIR RATIO FOR ENGINE C AT 600 RPM

ranges from approximately 2 to 3 per cent. It will be observed that individual points are dispersed at the lowest values of $\frac{fF - f_1F_1}{F - F_1}$ (see Fig. 16). This occurs because the different $b - b_1$ cannot be determined precisely when this difference is low. For example, an absolute error of 0.2 hp represents a relative error of 10 per cent when $b - b_1$ is of the order of 2 hp.

The values of the parameters e_0 and a were determined by the method of averages (7) and are given in Table 4. In determining the average points the data for each engine speed were divided into two groups above and below an arbitrarily selected value of $\frac{fF - f_1F_1}{F - F_1}$. The values selected were in the middle of the range of this term and were as follows: 0.04 for tests of engine A; 0.05 for tests of engine B; and 0.045 for tests of engine C. Table 4 also shows values of $\frac{e_0}{a}$ as these are required in a subsequent section of the report.

TABLE 4 VALUES OF e_0 AND a IN RELATION $e = e_0 - af$

Engine	Engine speed, rpm	e_0	a	$\frac{e_0}{a}$
A	600	4.13	22.7	0.182
A	1000	4.28	23.6	0.181
A	1400	4.42	24.4	0.181
B	1000	3.98	20.6	0.194
C	600	3.66	19.2	0.191

It will be observed that the values of e_0 and a appear to be affected by engine speed and type of engine. Therefore each set of values applies only to a particular engine and a particular engine speed. However, from the limited data available it appears that $\frac{e_0}{a}$ is approximately the same for the three engines tested and may not be affected by engine speed. If this is true for a number of engines, it would be possible to develop one set of correction factors applicable to all engines.

In connection with the apparent constancy of $\frac{e_0}{a}$, it is of interest to note that $\frac{e_0}{2a}$ is the fuel : air ratio at which both derived indicated horsepower and brake horsepower pass through a maximum. This can be shown by substituting for F its value $fQv\rho$ in Equation [3] or [5]; taking the derivative of i or b with respect to f; equating the derivative to zero and solving for f. Since the fuel : air ratio at which maximum horsepower is obtained is a function chiefly of the thermodynamic properties of the working fluid, it is not surprising that $\frac{e_0}{a}$ which is twice this ratio should be approximately the same for different engines. It should be pointed out that Equation [1] only approximates derived indicated efficiency at fuel : air ratios on the rich side and therefore $\frac{e_0}{2a}$ probably is not the exact fuel : air ratio that results in maximum power. Nevertheless $\frac{e_0}{2a}$ is an approximation of this particular fuel : air ratio and therefore it is not unreasonable to expect that it has the same general property of being determined principally by thermodynamic considerations and of being more or less independent of engine design.

From the foregoing it is apparent that we have a relation that is independent of ambient conditions and that can therefore be used in the development of rational procedures for correcting power output to standard ambient conditions. It is not claimed that the value of e obtained from Equation [1] is the true indicated efficiency, and for that reason it has been called derived indicated efficiency. Although the value of e is somewhat empirical, nevertheless we can operate algebraically with Equation [1] since it represents actual test data with reasonable precision.

The evaluation of the parameters e_0 and a permits evaluation of the parameter c in Equation [5]. It will be remembered that c is designated as "derived friction horsepower." Solving Equation [5] for c we obtain

$$c = (e_0 - af)F - b \qquad [9]$$

Since the values of b, F, and f are known for any test condition it is possible to determine c.

The values of c obtained using the values of e_0 and a for the engine and engine speed in question (see Table 4) are given in Table 5. Values of $\frac{c}{Q}$ are also given as they are required in a subsequent section of the report.

It will be observed that the average values of derived friction horsepower given in Table 5 are always greater than the friction horsepower determined in motoring tests (except for engine B at 30 inches absolute pressure and normal temperature). In general, the value of c tends to decrease as the ambient pressure is reduced. This same tendency was observed in the friction horsepower determined in motoring tests. The maximum and minimum values of c for each series of tests are given in Table 5 and indicate that at a given engine speed c is "constant" within reasonable limits. The computed values of c did not appear to be related to fuel : air ratio.

METHODS OF CORRECTING POWER-OUTPUT DETERMINATIONS TO STANDARD AMBIENT CONDITIONS

Derivation of Relations. Starting with Equation [1] which is independent of ambient conditions, we can derive expressions for converting measurements of power output to standard ambient conditions. Several expressions can be derived depending upon which parameters are retained. One such expression is derived in this section and two other forms of the correction equation are given.

If the subscript s denotes standard ambient conditions and the

[a] Values of c in tests at fuel:air ratios greater than the chemically correct value not included in average.

subscript t denotes ambient conditions at the time of a test, then from Equation [3]

$$i_s = (e_0 - af_s)F_s \quad [10]$$

and

$$i_t = (e_0 - af_t)F_t \quad [11]$$

In converting power output to standard ambient conditions the rate of fuel consumption must be the same at the standard condition as at the test condition; therefore

$$F_s = F_t \quad [12]$$

and equating the values of F_s and F_t determined from Equations [10] and [11], we obtain

$$\frac{i_s}{e_0 - af_s} = \frac{i_t}{e_0 - af_t} \quad [13]$$

or

$$\frac{i_s}{i_t} = \frac{e_0 - af_s}{e_0 - af_t} \quad [14]$$

Subtracting 1 from both sides of Equation [14], we obtain upon simplification

$$\frac{i_s}{i_t} = 1 + \frac{1 - \frac{f_s}{f_t}}{\frac{e_0}{af_t} - 1} \quad [15]$$

Since

$$f = \frac{F}{Qv\rho} \quad [16]$$

then when $F_s = F_t$ we obtain

$$\frac{f_s}{f_t} = \frac{v_t\rho_t}{v_s\rho_s} \quad [17]$$

Substituting for $\frac{f_s}{f_t}$ in Equation [15] its value from Equation [17], we obtain

$$\frac{i_s}{i_t} = 1 + \frac{1 - \frac{v_t\rho_t}{v_s\rho_s}}{\frac{e_0}{af_t} - 1} \quad [18]$$

Without introducing a significant error it can be assumed that $v_t \doteq v_s$. The basis for this assumption is discussed in a subsequent section of this report. With this approximation Equation [18] becomes

$$\frac{i_s}{i_t} \doteq 1 + \frac{1 - \frac{\rho_t}{\rho_s}}{\frac{e_0}{af_t} - 1} = R \quad [19]$$

Equation [19] gives a relation for correcting indicated horsepower to standard ambient conditions. However, in practice the principal interest is in the correction of measurements of brake horsepower to standard ambient conditions. This may be done by substituting for i_s and i_t the values obtained from Equation [4] which gives

$$\frac{b_s + c_s}{b_t + c_t} = R \quad [20]$$

Equation [20] is not in a convenient form unless the value of c_s is known but from Equation [20] we may obtain the relation

$$\frac{b_s}{b_t} = R + \frac{c_tR - c_s}{b_t} \quad [21]$$

The value of c is not affected to a great degree by changes in ambient conditions. Therefore, as a close approximation we can assume $c_s \doteq c_t$ and we obtain

$$\frac{b_s}{b_t} \doteq R + \frac{c_t}{b_t}(R - 1) \quad [22]$$

Substituting in Equation [22] the value of R from Equation [19] and rearranging we obtain

$$\frac{b_s}{b_t} \doteq 1 + \frac{\left(1 - \frac{\rho_t}{\rho_s}\right)\left(\frac{c_t}{b_t} + 1\right)}{\frac{e_0}{af_t} - 1} \quad [23]$$

When e_0 and a are known Equation [23] can be used to correct to standard ambient conditions measurements of power output made at any ambient condition. It is necessary to know the fuel : air ratio at the test condition and the value of c_t. This latter factor can be computed from Equation [9] or it can be determined in a motoring test. A relatively large error in c_t has comparatively little effect on the value of the ratio $\frac{b_s}{b_t}$.

By retaining different parameters in the correction equation other forms may be obtained. The following form contains the parameters a and c

$$\frac{b_s}{b_t} = 1 - \frac{c_s - c_t}{b_t} - \frac{aF_t^2}{Qb_t}\left(\frac{1}{v_s\rho_s} - \frac{1}{v_t\rho_t}\right) \ldots\ldots [24]$$

With the simplifying assumption made previously, Equation [24] becomes

$$\frac{b_s}{b_t} \doteq 1 - \frac{aF_t^2}{Qv_tb_t}\left(\frac{1}{\rho_s} - \frac{1}{\rho_t}\right) \doteq 1 - \frac{af_tF_t}{b_t}\left(\frac{\rho_t}{\rho_s} - 1\right) \ldots [25]$$

Another form containing the parameters e_0 and c is as follows

$$\frac{b_s}{b_t} = \frac{e_0F_t}{b_t}\left(1 - \frac{v_t\rho_t}{v_s\rho_s}\right) + \left(1 + \frac{c_t}{b_t}\right)\frac{v_t\rho_t}{v_s\rho_s} - \frac{c_s}{b_t} \ldots\ldots [26]$$

With the simplifying assumptions made previously, Equation [26] becomes

$$\frac{b_s}{b_t} \doteq \frac{e_0F_t - c_t}{b_t}\left(1 - \frac{\rho_t}{\rho_s}\right) + \frac{\rho_t}{\rho_s} \ldots\ldots\ldots\ldots [27]$$

Correction of Test Results to Standard Ambient Conditions

The test results have been corrected to standard ambient conditions of 29.92 in. of mercury and 60 F[4] by using Equation [23]. This equation has been selected for illustrative purposes, although either Equation [25] or [27] could be used. Figs. 18, 19, 20, and 21 show brake horsepower at standard ambient conditions (corrected brake horsepower) in relation to fuel consumption. It will be observed from these figures that a single curve represents the relation between corrected brake horsepower and fuel consumption regardless of the ambient conditions of the tests. In general the average deviations from the average curve are of the order of 0.5 hp or less. Part of this deviation is caused by normal experimental errors; part is caused by deviations of actual results from the average relation between derived indicated efficiency and fuel : air ratio; and part is caused by the simplifying assumptions made in deriving Equation [23]. The largest deviations of corrected brake horsepower from the average curve occurred in two tests of engine B at the highest rate of fuel consumption and at an ambient pressure of 20 in. of mercury (see Fig. 20). In these two tests the fuel:air ratios (0.0706 and 0.0840 lb per lb, respectively) were greater than the chemically correct value of 0.068. At these high fuel : air ratios combustion is incomplete and the derived indicated efficiency is not linear with fuel : air ratio (see Fig. 7). Therefore actual test results are not represented precisely by the average curve.

From the foregoing it is apparent that Equation [23] yields reasonably precise results when used to convert brake horsepower at test ambient conditions to brake horsepower at standard ambient conditions. The same order of precision of corrected brake horsepower may be obtained by using either Equation [25] or Equation [27]. It appears therefore that the principles outlined here may be useful in developing rational methods for correcting brake-horsepower determinations to standard ambient conditions. However, before such methods can be developed for universal application it will be necessary to obtain information on many more engines and to study the performance of each engine more intensively than was possible in the Bureau of Mines investigation. As mentioned previously, this investigation was concerned principally with the effect of ambient conditions on exhaust-gas composition, and performance data were obtained only incidentally.

The principal reason for choosing Equation [23] for illustrative purposes is that it can be put into a form convenient for graphical representation, which enables us to obtain a general idea of the magnitude of correction factors for power output of Diesel engines over a wide range of conditions. The value of $1 + \frac{c_t}{b_t}$ can be expressed in terms of fuel : air ratio and known parameters by utilizing Equations [5] and [16], which gives

$$1 + \frac{c_t}{b_t} = \frac{1}{1 - \dfrac{c_t}{(e_0 - af_t)Qv_t\rho_tf_t}} \ldots\ldots [28]$$

[4] This represents a commonly used engineering standard condition. The A.S.M.E. Test Code for Internal Combustion Engines, September, 1943, refers gas volumes to a standard condition of 29.92 in. of mercury and 68 F. The maximum difference between horsepower corrected to either condition is less than 0.9 per cent.

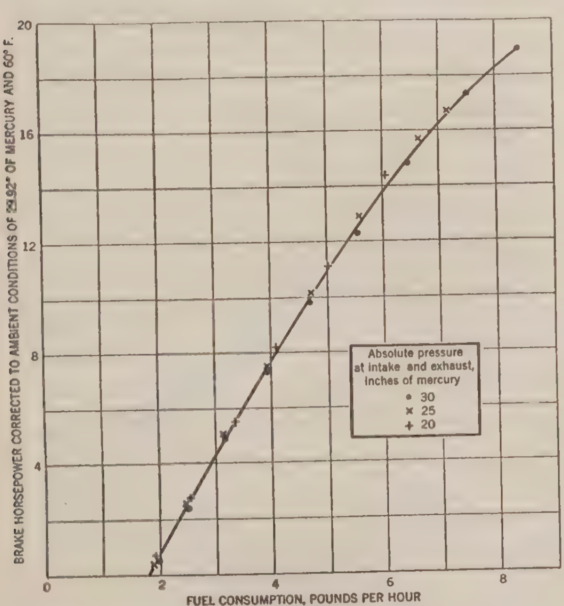

Fig. 18 Relation Between Corrected Brake Horsepower and Fuel Consumption for Engine A at 600 Rpm

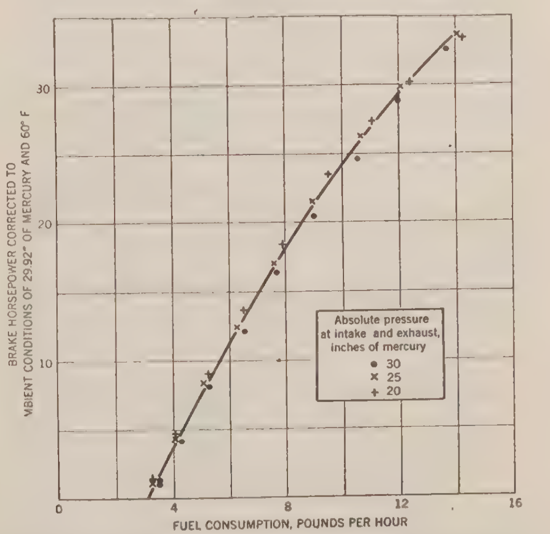

Fig. 19 Relation Between Corrected Brake Horsepower and Fuel Consumption for Engine A at 1000 Rpm

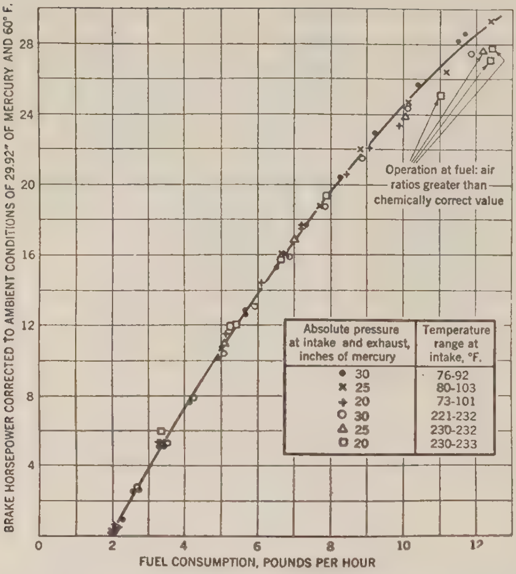

FIG. 20 RELATION BETWEEN CORRECTED BRAKE HORSEPOWER AND FUEL CONSUMPTION FOR ENGINE B AT 1000 RPM

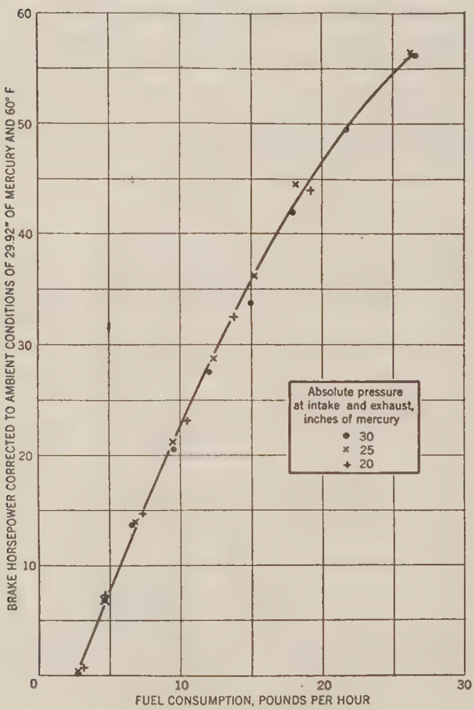

FIG. 21 RELATION BETWEEN CORRECTED BRAKE HORSEPOWER AND FUEL CONSUMPTION FOR ENGINE C AT 600 RPM

Substituting in Equation [23] the value of $1 + \frac{c_t}{b_t}$ from Equation [28], we obtain upon simplification

$$\frac{b_s}{b_t} \doteq 1 + \frac{1 - \frac{\rho_t}{\rho_s}}{\frac{e_0}{af_t} - \frac{c_t}{Qaf_t^2 v_t \rho_t} - 1} \qquad [29]$$

Equation [29] shows that $\frac{b_s}{b_t}$ can be expressed in terms of $\frac{\rho_t}{\rho_s}$ and f_t when the values of e_0, a, c_t, Q, and v_t are known. If we use the data for engine B and assume $e_0 = 3.98$, $a = 20.6$; $c_t = 7.2$; $Q = 3930$; and $v_t = 0.85$ (range of values of v_t for all test conditions at normal temperatures was 0.88 to 0.82) we obtain

$$\frac{b_s}{b_t} = 1 + \frac{1 - \frac{\rho_t}{\rho_s}}{\frac{0.194}{f_t} - \frac{0.000105}{f_t^2 \rho_t} - 1} \qquad [30]$$

Equation [30] is shown graphically in Fig. 22 for an assumed ρ_s of 0.0765 lb per cu ft (corresponding to an absolute pressure of 29.92 in. of mercury and a temperature of 60 F). From this figure we may obtain an excellent idea of the approximate magnitude of the correction factor for brake horsepower throughout a wide range of possible operating conditions. It is emphasized that Fig. 22 applies only to one engine and one engine speed, and until further information is developed each engine and engine speed should be considered as an individual case in preparing charts similar to Fig. 22. However, from the data available it appears that correction factors for any engine and engine speed will be within a few per cent of the factors shown in Fig. 22, except at low fuel : air ratios. The reason for this is that the values of $\frac{e_0}{a}$ and a do not vary greatly with type of engine and engine speed. Furthermore the value of $\frac{c_t}{Q}$ is not affected greatly by engine speed within the range studied because both c_t and Q are a function

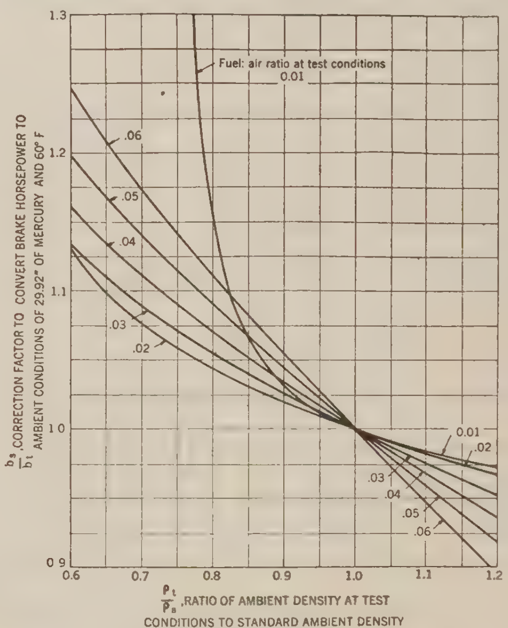

FIG. 22 RELATION BETWEEN $\frac{b_s}{b_t}$, $\frac{\rho_s}{\rho_t}$, AND f_t FOR ENGINE B AT 1000 RPM

(For assumed standard ambient conditions of 29.92 in. of mercury and 60 F.)

of engine speed. The value of $\frac{c_t}{Q}$ is affected by type of engine; however, a study of Equation [29] shows that comparatively large variations in $\frac{c_t}{Q}$ have relatively little effect on $\frac{b_s}{b_t}$ at the higher fuel : air ratios.

The most desirable form of the correction equation can be determined only when additional data are available. If further tests show that $\frac{e_0}{a}$ is approximately constant for a number of engines then it may be possible to use Equation [23] with an average value of $\frac{e_0}{a}$ for all engines except when extreme precision is required. The value of a may not vary widely from engine to engine, in which case Equation [25] might be more desirable.

The conditions under which correction factors may have a significant effect on measurements of power output of Diesel engines will depend principally upon the precision of the measurement of power output, on the ratio of the ambient density during the test to the standard ambient density, and on the fuel:air ratio at which the engine is operated during the test. In this connection it is interesting to note that the A.S.M.E. Test Code for Internal-Combustion Engines, September, 1943, permits a maximum deviation from specified operating conditions of ±3 per cent of the absolute barometric pressure specified and of ±5 per cent of the equivalent absolute temperature specified. Correction factors for power output are not required within these limits. With these permissible deviations it would be possible for ambient density to deviate ±8 per cent from the specified value. From Equation [30] it is evident that this deviation in ambient density would cause a deviation in specified brake horsepower of ±3.5 per cent in the case of engine B operated at a fuel:air ratio of 0.05 lb per lb. It appears, therefore, that in some instances consideration might be given to the application of correction factors for power output even though the test ambient conditions are within the permissible limits specified by the A.S.M.E. Test Code.

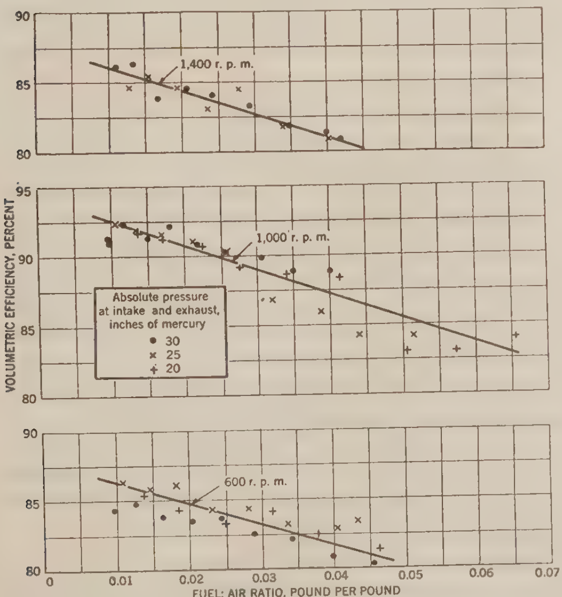

Fig. 23 Relation Between Volumetric Efficiency and Fuel: Air Ratio in Tests of Engine A

Effect of Ambient Conditions on Volumetric Efficiency

In deriving Equation [23], one of the simplifying assumptions was that volumetric efficiency was not affected significantly by changes in ambient conditions. It is of interest therefore to present the evidence supporting this assumption.

Figs. 23, 24, and 25 show the relation between volumetric efficiency and fuel:air ratio. It will be observed that volumetric efficiency decreases slightly as fuel : air ratio increases. The relation is apparently independent of ambient pressure within the range studied, as the deviations of volumetric efficiencies at different ambient pressures are generally within the limits of experimental error (approximately 2 to 3 per cent).

Fig. 24 shows a significant increase in volumetric efficiency as the temperature is increased. This apparent effect is a result of the method of heating the air and probably would not be observed if other more suitable arrangements were provided for heating the intake air. In the tests at elevated temperatures the intake air was heated electrically just before it entered the intake manifold. This method was used to avoid insulation of the intake surge tank. The addition of heat to the intake air results in an expansion in volume and therefore the work done during this expansion, which occurs at substantially constant pressure, must be considered. Under the test conditions a relatively large mass of intake air was on the upstream side of the air heater and a relatively small mass was on the downstream side. It would appear therefore that most of the work resulting from expansion during

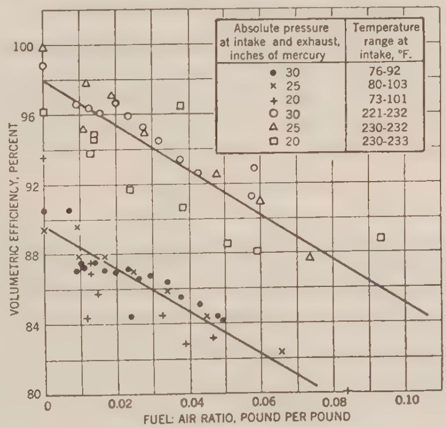

Fig. 24 Relation Between Volumetric Efficiency and Fuel: Air Ratio in Tests of Engine B at 1000 Rpm

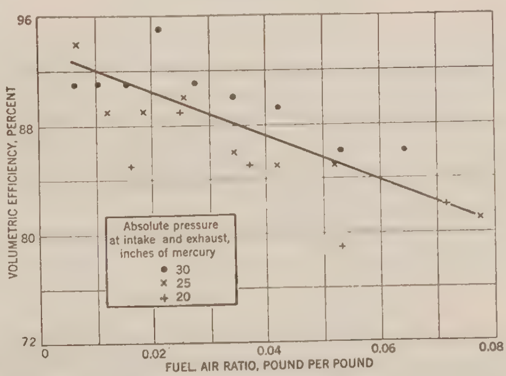

Fig. 25 Relation Between Volumetric Efficiency and Fuel: Air Ratio in Tests of Engine C at 600 Rpm

heating would be done on the relatively low mass of air downstream from the heater. It might be expected therefore that volumetric efficiency would be improved. It is believed that the foregoing explanation of the apparent effect of temperature is correct but additional experimental evidence will be required before it can be stated definitely that ambient temperature has no significant effect on volumetric efficiency.

In a Diesel engine operated at constant speed, changes in ambient conditions result in changes in fuel : air ratio if the throttle setting (rate of fuel consumption) is maintained constant. Accordingly, volumetric efficiency will be affected slightly by ambient conditions. If it is assumed that the ratio of ambient density during the tests to standard ambient density is as low as 0.6 the volumetric efficiencies under the two conditions do not differ by more than 3 per cent in any of the engines tested. If this difference were taken into consideration in Equation [23] the correction factor would be approximately 1 per cent greater at the high rates of fuel consumption.

If it is desired, volumetric efficiency can be related to fuel : air ratio by an equation of the following form

$$v = v_0 - df \quad [31]$$

in which v_0 and d are constant for a given engine and engine speed. This equation could then be used to determine the ratio of $\frac{v_s}{v_t}$. However, for the ordinary range of ambient conditions encountered it is doubtful whether this refinement is necessary.

Predicting Engine Performance by Algebraic Relations

The equations developed in preceding sections may be used to predict engine performance at any given ambient condition and rate of fuel consumption. From Equations [5] and [16] we obtain

$$b = \left(e_0 - \frac{aF}{Qv\rho}\right) F - c \quad [32]$$

In applying Equation [32] an average value of v may be assumed without introducing a significant error. If desired, v can be eliminated from Equation [32] by the use of Equation [31] but the resulting relation is much more inconvenient to handle.

For purposes of illustration, Equation [32] will be applied to the results of tests of engine B at 1000 rpm. The values of the parameters are as follows: $e_0 = 3.98$; $a = 20.6$; $Q = 3930$; $v = 0.85$ (range 0.82 to 0.88); $c = 7.2$; and Equation [32] becomes

$$b = 3.98\,F - 0.00640\,\frac{F^2}{\rho} - 7.2 \quad [33]$$

A comparison of observed values of brake horsepower and values calculated from Equation [33] is given in Table 6. This comparison shows that the equation can be used to predict the brake horsepower of engine B in its normal operating range with a maximum error of 0.7 hp. The error is greater when the engine is operated on the rich side (see Table 6, test 91) because under these conditions a linear relation between indicated efficiency and fuel : air ratio no longer holds.

If desired, Equation [33] can be represented graphically to show the relation between b, F, and ρ.

Summary and Conclusions

This report presents the results of performance tests on three different commercial Diesel engines at different ambient conditions. Operation at different ambient conditions was simulated by controlling conditions in surge tanks connected to the intake and exhaust of the engines. The tests were limited in scope because the principal interest in the investigation was the effect of ambient conditions on composition of the exhaust gases produced by the engine.

The performance data were analyzed, and a method was developed for deriving a relation between so-called derived indicated efficiency and fuel:air ratio that is independent of ambient conditions. The existence of such a relation would be predicted from theoretical thermodynamic considerations. The report presents a method for deriving the relation between indicated efficiency and fuel:air ratio from determination of brake horsepower, fuel consumption and fuel:air ratio at different loads throughout the operating range at a given engine speed.

The relation between derived indicated efficiency and fuel:air ratio is used as the basis for developing rational procedures for correcting to standard ambient conditions brake-horsepower determinations made at ambient conditions prevailing during the tests. The methods developed were applied to the results of tests at different ambient conditions and it was shown that the corrected brake horsepower at a given rate of fuel consumption was independent of the ambient conditions during the tests. Thus the methods developed appear to be suitable for determination of correction factors at least for the three engines on which data were obtained.

The relation between derived indicated efficiency and fuel:air ratio may also be used as the basis for algebraic expressions which permit determination of the brake horsepower of an engine at any rate of fuel consumption and at any ambient density when all the parameters in the equation are known. Brake horsepowers computed from the derived equation are in very good agreement with brake horsepowers determined in tests at a wide range of ambient conditions.

The data and analysis presented in this report have shown that rational procedures can be developed for correcting brake-horsepower determinations to standard ambient conditions. However, only three engines were tested and these engines were not studied as intensively as would be required in the development of generally applicable procedures for determining corrected brake horsepower. Further work may show that the parameters in the correction equation are not significantly different for different engines, in which case a single equation may be used for all engines. If this is not true, the correction equation will differ for different engines. There are indications also that these parameters may be affected by engine speed.

In an extensive study of methods for determining corrected brake horsepower it would be highly desirable to determine indicated horsepower directly and from this to determine whether ambient conditions have a significant effect on the relation between indicated efficiency and fuel:air ratio. If this were done it would not be necessary to derive an empirical relation from data on brake horsepower, fuel consumption, and fuel : air ratio as outlined in this paper.

Direct determination of indicated horsepower would also permit determination of the effect of ambient conditions on friction horsepower and of the effect of engine load on friction horsepower. If this fundamental information were available, more precise

methods could be developed for determining corrected brake horsepower.

Surge tanks connected to the intake and exhaust were used in the present investigation because of their simplicity and availability. However, in an extended investigation it probably would be advisable to test engines in a chamber in which the desired ambient conditions are maintained.

Acknowledgments

The author gratefully acknowledges the encouragement and support given to work on Diesel engines by A. C. Fieldner, chief, Fuels and Explosives Branch, and Wilbert J. Huff, consulting explosives chemist, Explosives Division, Bureau of Mines.

Particular acknowledgment is due to A. P. Rowles, principal engineering aide, Explosives Division, who obtained all test data, and to C. J. Ney, explosives testing station assistant, Explosives Division, and G. H. Hindman, assistant physical science aide, Explosives Division, who assisted in the test work.

The author is also grateful for the encouragement given by members of the A.S.M.E. Special Research Committee on Internal-Combustion Engines and particularly for the interest shown by Lee Schneitter, chairman.

Water Injection in a Spark-Ignition Engine

By W. P. GREEN[1] and C. A. SHREEVE, JR.[1]

The present war witnessed a revival of interest in the use of water as a coolant and detonation suppressor inside the engine cylinder. Aircraft engines when operated with water injection have been boosted in output above normal sea-level capacity and have functioned satisfactorily. This paper gives a review of past tests on the use of water as a coolant and detonation suppressor in gasoline engines. It presents new data regarding the use of water in very high compression ratio engines to promote increased part-load efficiencies with low octane fuels.

THE introduction of water into the mixture, entering the cylinder of a spark-ignition engine, was tried as early as 1866, and was common on carbureted engines burning kerosene a few decades ago. Its action was not fully understood but its purpose was to prevent detonation and to promote smooth combustion. In 1935 Ford L. Prescott reported tests on supercharged aircraft engines in which as much as 2.83 lb of water were added per lb of fuel. No loss in thermal efficiency and an increase in power output were noted. M. S. Kuhring has reported tests in which water was injected into the mixture at the supercharger, with results similar to those obtained by Prescott. Kuhring noted cooling effects on the spark plugs, cylinder heads, and valves when the water was injected.

Colwell, Cummings, and Anderson have presented results of recent work on the injection of water, and water-alcohol into the mixture of truck engines. Data are given to show no increase in wear or other harmful effects on engine life as a result of using water in the combustion chamber.

Steinitz has pointed out that the use of water with its attendant equipment complicates the engine and increases weight. Also there is the possibility of the water freezing unless mixed with an antifreeze solution.

Past research has established the following facts in regard to use of water injection as a detonation suppressor:

1 There is no loss of thermal efficiency with low rates of water injection.

2 Cooling of the engine is not so important a problem at high outputs.

3 Supercharged engines will give higher outputs due to cooling of the mixture by the injected water. The higher manifold pressures increase maximum cylinder pressures and engine output. Detonation is suppressed by the water.

4 Space and weight requirements for carrying the water may be excessive unless condensing equipment is used to secure water from the exhaust gases.

5 There is danger of the water freezing unless mixed with an antifreeze solution.

Purpose of Present Tests

In the light of previously published information the authors felt that tests conducted over a wide range of compression ratios and rates of water injection would accomplish the following:

1 Add valuable data as to quantity of water needed to prevent detonation at a number of load conditions and compression ratios.

2 Determine whether worthwhile gains could be made by operating an overcompressed engine without water at low loads, with detonation suppressed in the high load range by water injection.

3 Indicate effect of injected water on such items as exhaust temperature and heat loss to cooling water.

Test Equipment. A single-cylinder water-cooled N.A.C.A. Universal test engine, located in the mechanical-engineering laboratories of the University of Maryland, was used for all tests, Fig. 1. This engine has a 5-in. bore and 7-in. stroke. Its

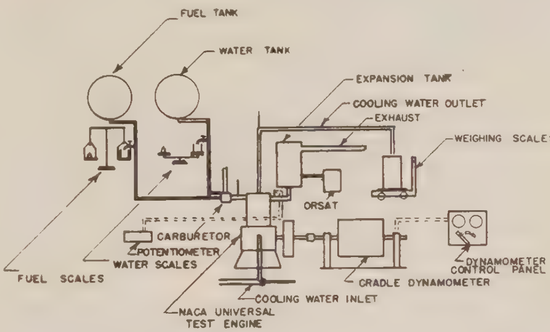

Fig. 1 Schematic Layout of Test Equipment

compression ratio may be continuously varied from 4 to 1 to as high as 14 to 1. The engine is equipped with a valve-in-head combustion chamber, with two intake and two exhaust valves. A magneto ignition system was used with a single spark plug located at the top of the combustion chamber. Engine output and friction horsepower were measured with a Sprague-type electric dynamometer.

Water was fed from a $^1/_2$-gal beaker, mounted on a weighing scale, to a small jet located in the carburetor venturi. Flow of water was controlled manually.

A standard fuel-weighing set-up was used to measure fuel-consumption rates. Mixture temperatures were measured with a thermometer inserted in the intake manifold 10 in. from the intake-valve port. Mixtures were checked during each test with an Orsat apparatus. Samples of exhaust gas analyzed were taken from an expansion tank located 4 ft from the engine-exhaust-valve port. Exhaust-gas temperatures were measured by an unshielded thermocouple located in the engine exhaust and read by a potentiometer. Exhaust temperatures were corrected for radiation and recovery losses as suggested by King (1)[2] and Hottel (2).

Cooling water from laboratory mains entered a recirculating system actuated by a pump on the engine. Its temperature was measured at the inlet to the recirculating system. After passing through the engine cylinder and head to a thermometer well at the outlet, the water was caught in a tank and weighed. An RCA piezoelectric indicator was used to take cards and to check detonation visually.

[2] Numbers in parentheses refer to the Bibliography at the end of the paper.

Test Procedure. It was decided to operate the engine on one type of fuel at four different throttle openings, thus varying the output between 30 per cent load and full load. At each throttle position tests were run at a number of compression ratios. The first run at each throttle opening was made at a low enough compression ratio so that no detonation occurred under normal operating conditions. No water was injected on this run. Succeeding runs were made at higher compression ratios with just enough water being injected to suppress detonation. Detonation was detected by ear and by the oscillograph on some tests.

Table 1 shows items which were maintained constant on all runs.

TABLE 1 ITEMS WHICH WERE CONSTANT DURING TEST RUNS

Fuel used	gasoline
Octane no. of fuel	68
Revolutions per minute	1000
Spark advance, deg Btdc	25
Air-fuel ratio (approx)	14:1
Cooling-water temperature in cylinder head and cylinder wall, deg F	180 ± 5
Oil temperature, deg F	125 ± 5
Oil pressure, psi	42
Exhaust pressure	atmospheric
Inlet air, deg F	60 ± 5
Mixture temperature, deg F	65 ± 3
Barometer reading, in. Hg	30 ± 0.10

The engine was operated for approximately $2^1/_2$ hrs, until readings indicated that all operating conditions were constant. Several test runs of 15 minutes were conducted at each compression ratio. Whenever the compression ratio was changed at least 30 minutes were allowed for conditions to stabilize before new test readings were taken.

Primary test data taken in addition to readings of standard conditions were as follows:

Compression ratio	Dynamometer load
Duration of run	Cooling-water temperature at inlet
Pounds of fuel consumed	Cooling-water temperature at outlet
Pounds of injection water	Pounds of cooling water
Average rpm	Exhaust temperature
Orsat analysis	

Results. Results computed from the data are plotted in Figs. 2, 3, 4, 5, and 6. Each figure shows the engine performance at one throttle opening for various compression ratios and throttle openings.

It is apparent from a study of these figures that as the load is increased, water injection must start at lower compression ratios in order to prevent detonation. If, however, effective compression ratios are considered, it is necessary to start water injection at compression ratios between 4.2 and 5.1 to 1 for all tests on this engine.

Indicated horsepower, brake horsepower, and thermal efficiency show marked gains with increase in compression ratio, especially in the case of throttle opening No. 1. At compression ratios larger than 11:1 there is no appreciable gain in efficiency and power due to the action of the injected water.

Exhaust temperatures and heat to cooling water decrease rapidly with increased compression ratios and water rates.

Fig. 6 shows a typical mechanical-efficiency curve for this engine. It was found that the variations in throttle opening and compression ratio had little effect on this curve. All points fell within ± 2 per cent of the curve.

Quantities and Effects of Injection Water

Fig. 7 shows a family of curves indicating the pounds of water required per pound of fuel to prevent detonation for various horsepower and compression ratios on this engine. It will be noted that higher outputs and compression ratios required higher rates of water injection. In connection with these curves, it should be noted that in the high-load and compression-ratio ranges the engine did not detonate although it ran roughly and occasionally misfired. It is possible that misfiring could have been prevented by use of other types of spark plugs, although this was not investigated.

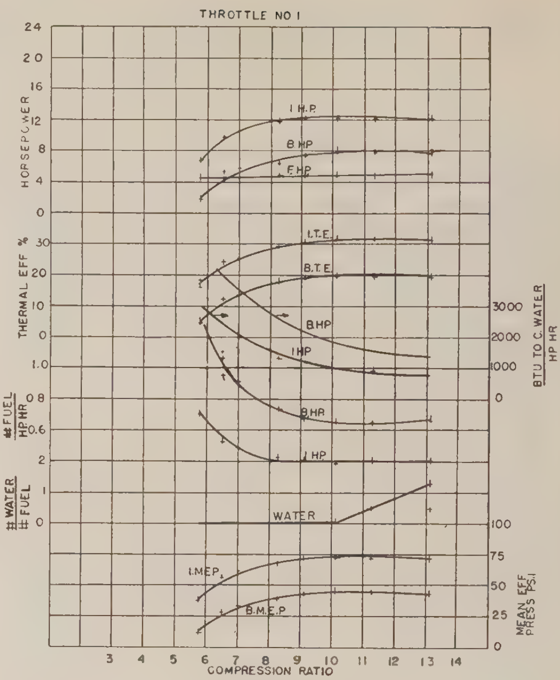

Fig. 2

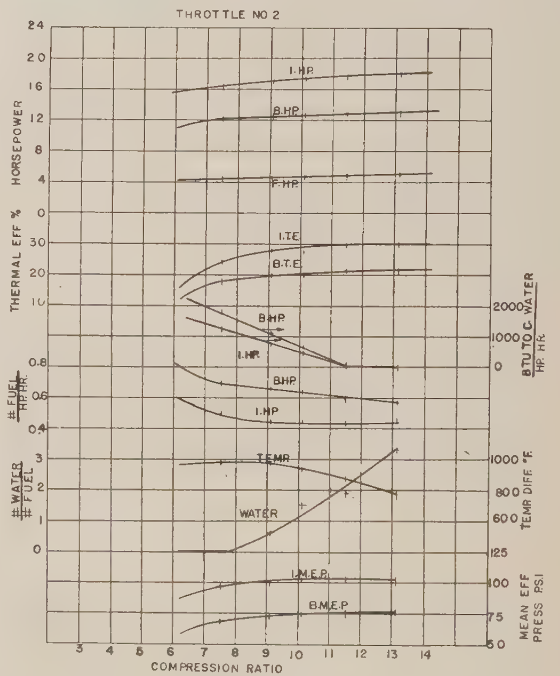

Fig. 3

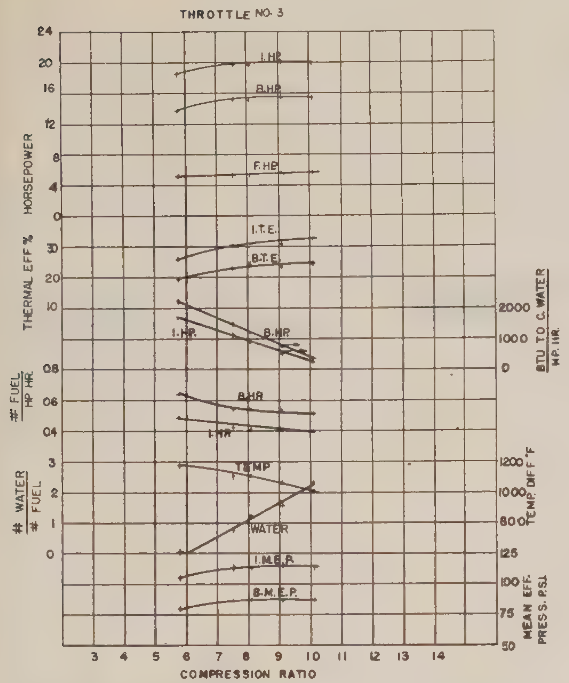

FIG. 4

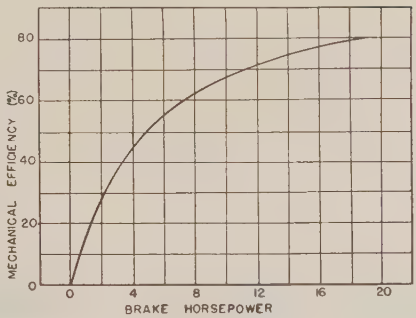

FIG. 6

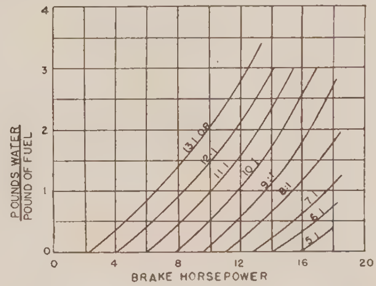

FIG. 7

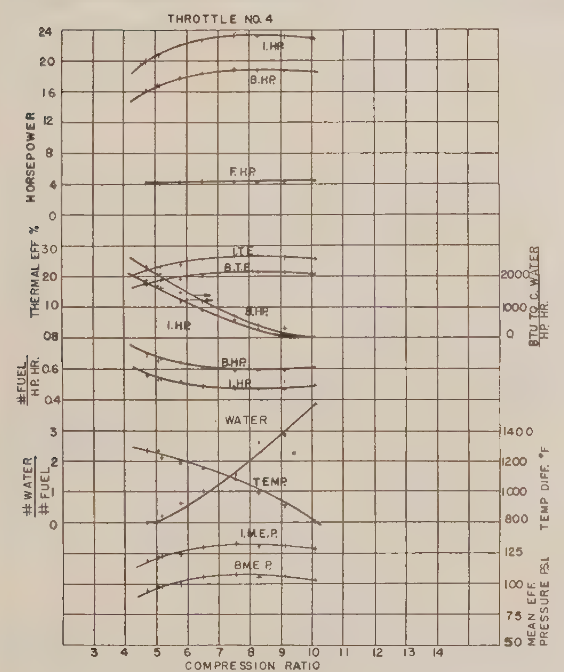

FIG. 5

Fig. 8 shows a set of typical pressure-time-indicator cards for this engine at full throttle and with various compression ratios, using a slightly different gasoline from that of the preceding tests.

At the 4.8:1 compression ratio it was not necessary to add water to prevent detonation. At 5.2:1 compression ratio slight detonation was evidenced by the sharp peak at the top of the card. This was remedied on the next card by the addition of just enough water to prevent detonation. It will be noted that the first effect of the water was to lower the maximum pressure.

As the compression ratio was increased it was necessary to increase the water-injection rates to prevent detonation. It will be noted that the effect of high rates of water injection was to decrease the slope of the expansion line to a marked degree.

The 9:1 compression-ratio card has an excess of water and definitely shows the effect of the water vapor on the expansion line.

Fig. 9 shows the effect of the addition of water on the cooling loss (Btu/bhphr). This curve indicates that the heat loss to cooling water is largely dependent on the water-injection rate. It also shows that for higher rates of water injection the cooling problem is reduced to a point where it is possible that no external cooling other than that done by radiation and the lubricating oil will be required.

Fig. 10 shows the effect of brake horsepower and compression ratio on brake specific fuel consumption. Water was added where necessary to prevent detonation in the amounts indicated in Fig. 7. At the lower brake horsepowers there is a marked difference between the specific fuel consumption at the various compression ratios, while at the higher outputs the water required to suppress detonation lessens the gains due to higher compression ratios.

Fig. 11 shows a comparison between the fuel required for the various compression ratios in per cent of fuel required for 6:1 compression ratio. At the lower loads the 11:1 compression ratio will save about 50 per cent of the fuel required at the 6:1 compression ratio. As the load increases the fuel economy due to the higher compression ratio decreases until at full load the amount of injected water may actually make the higher ratio slightly less economical.

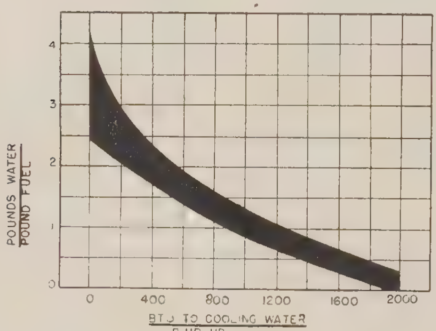

Fig. 9

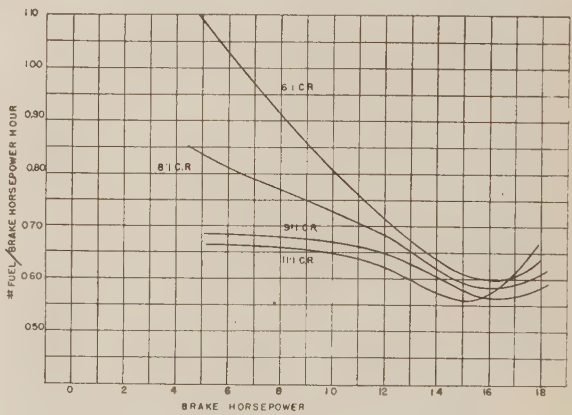

Fig. 10

Conclusions

The injection of water into the engine cylinder decreases the maximum pressure and tends to decrease the slope of the expansion line with little or no change in thermal efficiency.

Savings shown by the curves in Fig. 11 indicate the desirability of the use of water injection in engines that will operate the greater portion of the time in the low-load range, with only occasional use at full power.

Exhaust temperatures are reduced by water injection although a portion (or all) of the normal heat transferred to the cooling water now appears in the exhaust.

Relation Between the Impact and Flexural Tests for Molded Plastics

By L. E. WELCH[1,2] and H. M. QUACKENBOS, JR.[1]

A theoretical treatment of the phenomena of impact is presented which indicates that rupture under dynamic stress-strain conditions results from the same basic considerations as those governing static or flexural failure. This thesis is proved experimentally by reducing the problem to one of stress rather than the usual method of energy evaluation. When this is done with the aid of newly developed high-speed electronic techniques, it is conclusively demonstrated that impact loading is merely a special case of static loading whereby the stress-strain conditions are identical except for a slight elevation in strength under dynamic conditions. It is shown that the existing methods of impact-strength evaluation such as the standard Izod and Charpy tests lead to erroneous results since the machines in use are apparently of too light a construction, and the technique is oversimplified. It is suggested that the static flexural-test technique when properly carried out to evaluate the energy required for fracture and the notch sensitivity, is sufficient to predict the service characteristics of essentially brittle materials under conditions of both static and impact loading.

Nomenclature

The following nomenclature is used in the paper:

A, B = constants in Equation [16]
b = width of specimen
E = modulus of elasticity of specimen
g = gravitational acceleration
h = depth of specimen (taken outside notched area where bar was notched)
I = moment of cross section of specimen
K, K_M, K_S = spring constant of system, machine and specimen, respectively
l = distance from plane of loading to center of gage for cantilever
L = span of specimen, or length in Equation [4]
M = mass of impacting element
P = force exerted in either static or dynamic loading
t = time after impact
t_1 = total time duration of nonfracture impact
u = mass per unit length of specimen
U = strain energy in specimen under flexural or impact loading
U_0 = kinetic energy of falling (impacting) element
U_S, U_M = energy stored in specimen spring and machine spring, respectively
w = frequency of natural vibration of specimen
v_0 = velocity of impacting element at moment of impact
ϵ = maximum strain in specimen
σ = maximum stress in specimen
y = deflection of specimen in bending test
y_M, y_S = deflection of machine spring and specimen spring, respectively, at any time during impact
y_M', y'_S = maximum values of y_M and y_S during impact

Introduction

Three tests have been generally accepted for evaluating the mechanical properties of rigid plastics. These are the tests for tensile, flexural, and impact properties. Of these the Izod and Charpy impact tests on a notched bar are the most valuable because they differentiate between materials that show similar tensile and flexural results. For example, with the phenolic-resin molding materials with which this paper is largely concerned, the flexural strength usually falls in the range 7000 to 15,000 psi, while the tensile strength displays a smaller variation. The type of filler (wood flour, fabric, mineral, etc.) is more responsible than the type of resin for these changes. The Izod impact strength, however, may vary from 0.15 ft-lb per notched specimen for the wood flour filled to 2.5 ft-lb and higher for the fabric filled. Moreover, the impact evaluation is usually a fair forecast of the toughness of a molded object, especially where internal corners exist. But there are many instances where the agreement between impact tests and practical experience breaks down completely, and so an examination of the Charpy and Izod tests for rigid plastics was undertaken.

A brief description of the flexural and impact tests can well precede a review of the literature. In the standard flexural test a molded specimen, $5 \times {}^1/_2 \times {}^1/_2$ in., is loaded on a 4-in. span. The load-deflection curve is often linear to failure and if ductility is exhibited, it is small. The usual modulus of elasticity (hereinafter referred to as simply modulus) for phenolic molding materials ranges from $1\text{–}4 \times 10^6$ psi. The Charpy and Izod machines are similar to those used for testing metals, except that they are of much lighter construction to accommodate the relatively brittle plastic materials. The standard Izod machine weighs approximately 120 lb. In each test the standard specimen is ${}^1/_2 \times {}^1/_2$ in. with a milled notch 0.100 in. deep, and with a radius of 0.010 in. at the bottom. The Izod specimen is a cantilever $1^1/_4$ in. long struck 0.866 in. above the point of clamping. The Charpy specimen is supported on a 4-in. span and is struck on the side opposite the centrally disposed notch.

The impact strength, that is, the energy loss of the pendulum, is usually considered to be composed of three main parts:

1 Actual strain energy to break the specimen.

2 Machine losses; vibration and damping in the base of the machine.

3 Energy lost by the pendulum in projecting the broken end (Izod) or ends (Charpy) of the specimen.

Item 3 has been the subject of several recent papers (1, 2, 3, 4, 5).[3] The "end effect" was eliminated either by lowering the

[1] Research and Development Laboratories, Bakelite Corporation, Bloomfield, N. J.

[2] East Orange, N. J.

[3] Numbers in parentheses refer to the Bibliography at the end of the paper.

pendulum in the orthodox tests until it possessed just enough energy to fracture the specimen, or by using a drop-weight machine in which the specimen is struck blows of increasing severity until fracture is caused. The energy associated with the end effect varies considerably with the filler. It is a small or negligible proportion of the measured impact strength with the tougher materials having a filler of fiber. With the more brittle wood-flour type the proportion may be 60 per cent and as high as 85 per cent with a high-density lead-filled composition. Consequently, quite a different comparison between the common molding materials is given when the end effect is eliminated.

With the energy of projection disposed of, the residual impact energy is then the sum of items 1 and 2, that is, the strain energy plus the machine losses. Most opinions place the machine losses as nearly zero (2, 3, 6). This leaves the residual impact energy as strain energy, and one could reasonably expect it to agree with the energy in a flexural test. Recent tension impact tests of metals (7, 8) have demonstrated that the same stress-strain behavior often occurs in both dynamic and static loading. Early work (9) on wood in long-span flexure shows the same agreement. A paper by Hazen (10) points out that the static flexural energy is a better criterion of service toughness than the standard Izod impact value. Yet the residual impact energy is about 25 per cent higher than the corresponding flexural energy in the Charpy test and is 3 or 4 times as high in the Izod test. The Izod flexural energy for the cantilever of 0.866 in. was calculated in the orthodox way, from the ratio of the spans, as 0.866/4 in. times the energy at a flexural span of 4 in., with a 32 per cent increase to allow for shear.

These discrepancies between the static and dynamic energies suggest the following possibilities: (*a*) The stress-strain relations under impact loading are different from those under static loading; (*b*) machine losses are appreciable.

To resolve these questions the stress-strain diagram in impact has been determined in the Izod and Charpy machines and compared with that for static loading at the same spans. The strain energy in impact absorbed by the specimen can be calculated from the relation between stress and strain. The difference between this energy and that applied by the pendulum, with the end effect eliminated, is taken as machine losses. As machine losses were appreciable, their variation with span was established in a drop-weight type of impact machine.

As to the stress-strain diagram in impact, the strain was measured with a resistance-wire strain gage cemented to the specimen. The voltage change across the gage on straining was amplified and passed to an oscillograph where the displacement of the oscillograph spot then became a measure of the strain. The measurement of dynamic strain in this fashion is an established technique in a number of laboratories (8, 11, 12). The determination of dynamic stress requires a delicate method (8) that could be avoided here because most of the materials used possess a linear stress-strain relation to failure. The dynamic modulus was calculated from the frequency of natural vibration and assumed equal to the modulus present under impact loading. The dynamic stress was derived as the product of this modulus and the measured strain.

Experimental Procedure

Experiments covered the range of common, phenolic molding materials having a variety of fillers and included work on cast iron and steel. All bars had a rectangular cross section. The molding materials were either molded as individual specimens or cut from molded plates 8 in. × 10 in. The laminated specimens were cut from plates. The cut surfaces were smoothed by grinding. The cast iron was cast as a single plate, 12 × 12 × $^3/_8$ in., and bars were cut therefrom 6 × $^3/_8$ × $^3/_8$ in. and finished by grinding. The single steel specimen used was 6 × $^1/_2$ × $^1/_2$ in. from cold-rolled stock. Some of the plastic specimens having a section $^1/_2$ × $^1/_2$ in. contained standard notches, 0.100 in. deep, 0.010 in. radius, milled in the center of one face. Table 1 summarizes the materials.

TABLE 1 LIST OF MATERIALS USED

Material	Description
BM-021	Phenolic resin + wood flour
BM-120	Phenolic resin + wood flour
BM-262	Phenolic resin + mica
BM-1914	Phenolic resin + kraft paper
BM-3510	Phenolic resin + fabric
BM-6260	Phenolic resin + wood flour + cotton floc
XM-9131	Pure phenolic resin — no filler
BM-13080	Phenolic resin + wood flour + cotton floc
BM-16468	Phenolic resin + fabric
Steel	
Cast iron	

The plastic specimens were conditioned 2 days at 50 C and were kept until tested in the laboratory maintained at 25 C, 50 per cent relative humidity.

The following tests were performed: To remove directional effects the same face (e.g., a top molded or cast face) was always in tension.

1 Flexural test on a span of 4 in., according to A.S.T.M. D790–44T: Load-deflection curves were recorded with a Templin stress-strain recorder which magnified the deflection 40 times. Spans other than 4 in. were used occasionally. The measured deflection includes deformation of the machine parts and indentation into the specimen of the edges for loading and supporting. A load-deflection curve was run at zero span (supporting edges together) to give a correction to the measured deflection. For the common thermosetting materials in the form of a bar of $^1/_2$ × $^1/_2$ in. cross section this correction is about 5 per cent at a span of 4 in.

With deflection corrected, modulus for an unnotched bar was calculated from the slope of the load-deflection curve according to

$$E = \frac{PL^3}{4ybh^3}\left[1 + \frac{3h^2}{L^2}\right] \quad [1]$$

and flexural energy from the area under the load-deflection curve.

Modulus was also measured by loading an unnotched bar having a strain gage cemented to the tension face of the specimen. The gage (Baldwin Southwark type SR-4, A-5, length $^1/_2$ in.) was connected to an SR-4 strain meter in the usual way. The center of the gage was vertically below the loading column. The observed strain for a given load must be multiplied by $L/(L - {}^1/_4)$ to give the maximum strain in the plane of loading. Load was converted to stress by

$$\sigma = 1.5\,\frac{PL}{bh^2} \quad [2]$$

and modulus calculated from the slope of the curve of stress versus maximum strain.

2 Static cantilever test: Modulus was determined with resistance-wire strain gages for a span of 0.866 in. If the center of the gage was distance l from the plane of loading, the stress by which the observed strain was divided to give the modulus was calculated from

$$\sigma = \frac{6Pl}{bh^2} \quad [3]$$

A notch, when present, was located on the tension side with its "vee" in the plane formed by the faces of the gripping members and a "modulus" was calculated as if the notch were absent.

3 Dynamic modulus: The frequency of natural vibration

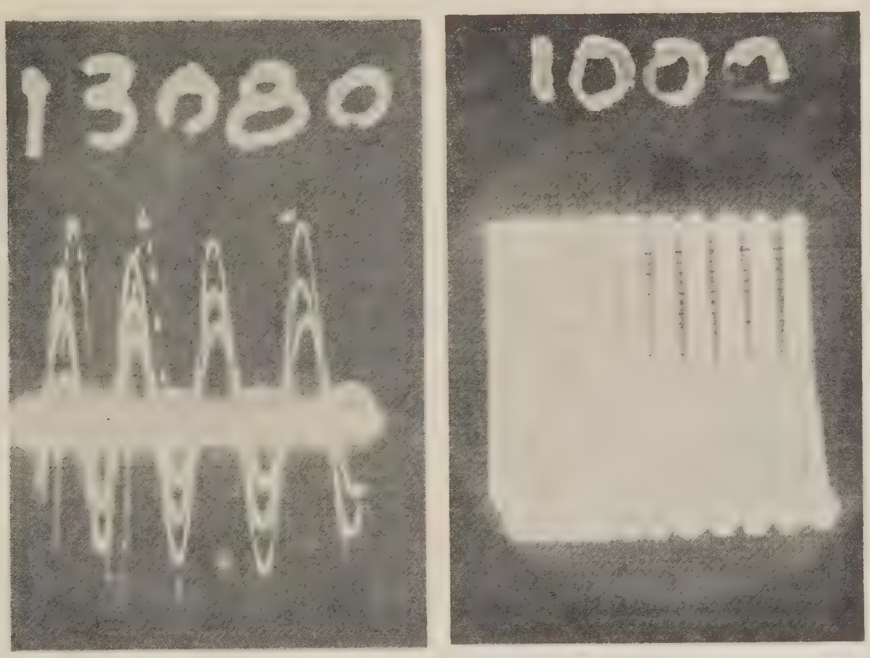

FIG. 1 FREQUENCY OF NATURAL VIBRATION FOR BM-13080, $^1/_2 \times ^1/_4$ IN. AND 1000 CYCLES PER SEC CALIBRATION

was determined mainly for bars having a cross section $^1/_2 \times ^1/_4$ in. An SR-4 A-5 gage was cemented to the central area of the specimen. The gage was connected into the dynamic-strain circuit described in the Appendix. With the oscillograph spot spread into a line, the vibrations of the bar when held lightly at one end and struck at the other cause a wave to appear on the screen of the oscillograph, Fig. 1. This wave is photographed and compared with a wave of 1000 cycles per sec induced by an oscillator. From the natural frequency w, modulus E is (13)

$$w = \frac{22.4}{L^2}\sqrt{\frac{EI}{u}} \qquad [4]$$

4 Measurement of applied impact energy: The Izod and Charpy machines were fitted with movable spring releases to allow the pendulum to be dropped from any desired height. The heights used were such that the impact velocity varied between 2 and 11.4 fps. The specimen was either given a light blow, insufficient to break, or a blow such that the swing-through after fracture was small. The energy applied to the specimen in either case is calculated as in the Appendix. The Izod machine is a standard type manufactured according to the specifications of the Bell Telephone Laboratories. The Charpy instrument was of lighter weight and was made in the bakelite machine shop.

In the drop-weight tester, Fig. 2, a grooved weight released magnetically slides down vertical stainless-steel wires. The base is a steel plate set in a concrete block, $18 \times 12 \times 4$ in. The energy is the product of the height and the weight with an allowance for friction established in a calibration with an electrical timer. The energy of fracture was determined by an increment method. The height was raised 10 per cent each time from an initial height adjusted so that 2 to 4 blows were needed for fracture.

5 Measurement of impact strain and time: The distribution of strain was established with A-8 gages which were good

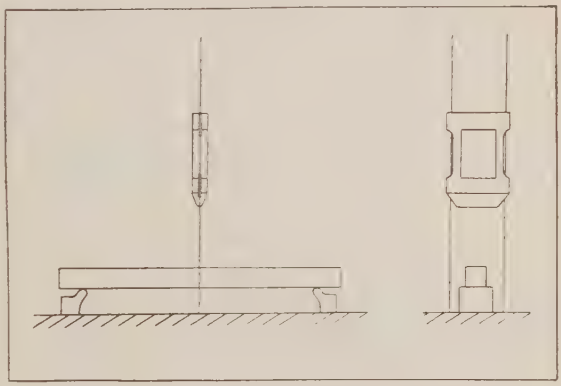

FIG. 2 THE DROP-WEIGHT IMPACT MACHINE, SHOWING WEIGHT SLIDING DOWN WIRES

indicators of essentially point conditions by virtue of their extremely small gage length of $^1/_8$ in. The A-8 gage was also used to detect any compression of the bar against the pendulum and against the supports. Fig. 3 illustrates the disposition of the gages for these experiments.

Once the strain was found to be distributed linearly, subsequent experiments were carried out with A-5 gages which are $^1/_2$ in. long. The maximum strain was calculated from the observed strain at a certain position assuming linear distribution.

With most experiments in which the bar was struck lightly the oscillograph beam of electrons was narrowed to a spot and its displacement was observed by eye as a mean of several blows. Photographs confirmed the precision of this visual method. When photographs were taken the circuit was modified so that the spot was traveling across the face of the oscillograph at a constant rate. The impact then appears as a loop with strain in

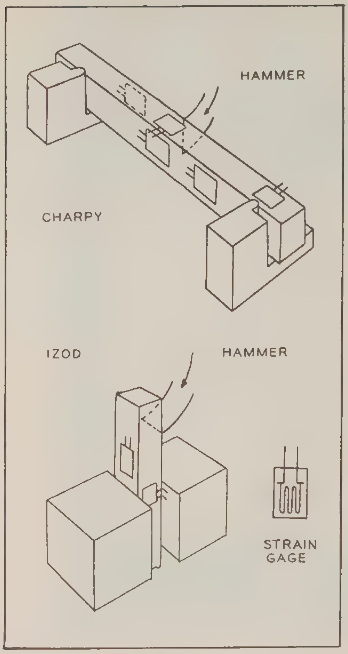

Fig. 3 Disposition of Strain Gages on Charpy and Izod Specimens

vertical units and time in horizontal units. The calibration of the vertical and horizontal units is described in the Appendix. Where the bar was broken photographs were taken with a Contax.

In any one set of tests all bars of one material were from the same batch but different batches were frequently used for different tests. This explains slight variations in modulus from test to test.

Discussion of Results

In analyzing the response of a bar to impact loading it is natural to compare with conditions under static loading. The criteria of comparison are modulus and distribution of strain.

Dynamic Modulus. The dynamic modulus is in most instances the same as the flexural modulus, Table 2. Later when

TABLE 2 DYNAMIC AND STATIC MODULI; 4 IN. SPAN

Material	Flexural modulus psi $\times 10^{-6}$	Dynamic modulus psi $\times 10^{-6}$
BM-120	1.25	1.20
BM-262[a]	4.66	4.55
BM-1914	1.53	1.69
BM-3510	1.47	1.80
BM-6260	1.13	1.14

Steel	29.5	(29.5)
Cast iron	10.5	(10.5)

[a] Specimen, $^1/_2 \times {}^1/_2$ in. All others $^1/_2 \times {}^1/_4$ in.
Note: Dynamic modulus assumed equal to static modulus for steel and cast iron.

calculations were made of impact strain energy in the specimen, the modulus used was the flexural modulus, except for BM-3510, BM-16468, and BM-1914, where the flexural moduli were increased 20 per cent, 10 per cent, and 10 per cent, respectively. Two simplifications are implied when calculations on this basis are made for specimens of various dimensions in the Charpy and Izod tests and for notched bars in the latter. These are as follows:

(*a*) While nearly all the results of Table 2 are for bars having a section $^1/_2 \times {}^1/_4$ in., they are assumed to hold for all dimensions.

(*b*) The static modulus for notched and unnotched cantilever beams (0.866-in. span) is the same as the flexural modulus (4-in. span). Actually the former (notched) tends to be a few per cent lower, and the latter (unnotched) the same degree higher, as established by strain gages.

Deformation Under Static and Dynamic Loading. Fig. 4 illustrates the variation with distance of the dynamic surface strain for a beam tested in the Charpy machine. In general this strain increases from zero at the supports to a maximum at the center, the point of striking, just as it would under similar flexural loading. This was true for several values of the span length and several specimens of different dimensions struck blows insufficient to cause fracture.

There were anomalous effects but these were small enough to be ignored: (*a*) The hammer knife-edge indents into the specimen causing a low compression strain at the point of impact, Fig. 4; (*b*) at the supports and at the striker a local compression wave travels between the surface being hit and the opposite face; (*c*) at the supports the bending strain is not quite zero.

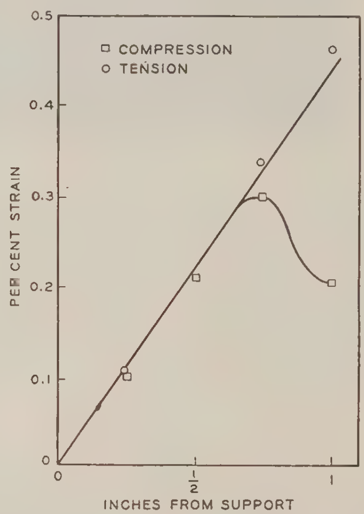

Fig. 4 Impact Strain Versus Distance From Support in Charpy Machine
(BM-021, Span = 2 in., b = 0.5 in., h = 0.5 in.)

Similar anomalies were observed in the unnotched Izod specimen, but otherwise the surface strain increased in linear fashion from the plane of striking to the plane of clamping.

Taken in conjunction with the agreement between the static and the dynamic modulus these findings permit the conclusion that strain, stress, and load build up from zero in the same way in both tests.

Energy Absorbed by the Impact Specimen. In these circumstances the impact strain energy can be computed from the measured impact strain by exactly the same equations that hold for static loading. The strain energy absorbed by a rectangular beam in reaching a maximum strain in flexure ϵ, at the surface, in the plane of loading is given by

$$U = \frac{1}{216} bhLE\,\epsilon^2 \left(1 + 3\frac{h^2}{L^2}\right) \qquad [5]$$

This is a standard textbook formula (14). The factor in parentheses allows for shear energy and is predicated on a value of

TABLE 3 ENERGY ABSORPTION IN CHARPY MACHINE FOR UNNOTCHED BARS STRUCK WITH BLOW INSUFFICIENT TO FRACTURE

Material	b in.	h in.	Span in.	Dynamic modulus, E, psi $\times 10^{-6}$	Measured absorption, per cent	Calculated absorption,[a] per cent

[a] Calculated absorption based on BM-021 as explained in text.
NOTE: Energy applied varied from 0.1 to 0.22 ft-lb; corresponding velocities of impact being 2 and 3 fps. All bars unnotched.

0.3 for Poisson's ratio, which is true for most plastics (15). The formula for a cantilever is similar (14)

$$U = \frac{1}{216} bhLE\,\epsilon^2 \left(1 + \frac{h^2}{L^2}\right) \quad [6]$$

where ϵ is now the strain at the grip.

A sample calculation for the Izod machine will illustrate the method. Material BM-021, $b = 0.50$ in., $h = 0.50$ in., no notch. Observed strain for gage with center 19/64 in. from grip = 3000 microinches per in. Maximum strain at grip = 3000 × 0.866/(0.866 — 19/64) = 4560 microinches per in.; $E = 1.25 \times 10^6$ psi. Hence energy absorbed by specimen U, from Equation [6] with L = 0.866 in. is 0.034 ft-lb. Energy applied by hammer = 0.131 ft-lb. Per cent measured absorption by specimen = 0.034/0.131 × 100 = 26 per cent. Measured absorptions for the Charpy machine are arrived at in the same way by means of Equation [5].

Measured absorptions calculated by these methods are listed in Tables 3 and 4 for the two impact machines. The significance of calculated absorption will be discussed later.

When the specimen does not break there are, of course, no end effects, and these have been eliminated from the applied energy when it does break. It is seen that generally not all the applied energy is absorbed by the specimen, the remainder presumably being lost to the machine. According to the figures presented, the per cent absorption varies from material to material in both machines and is especially erratic for specimens broken in the Izod test. Further, in the Izod test there is a considerable variation in energy absorbed from one specimen to another, sometimes as high as ±18 per cent. This in spite of the fact that the percentage absorption for one specimen struck lightly varies only ±6 per cent. Changes in clamping pressure seemed responsible to only a small extent.

In view of these findings, the energy lost by the pendulum, corrected for the end effect, has no absolute or comparative significance in either of the impact tests. The energy absorbed gives the correct answer, but even this is unsatisfactory in the Izod test because of its variability. A new test to replace the Izod test is suggested later in this paper.

There are certain disagreements in Table 4, as yet unexplained, between the energy absorption at fracture and that under a light blow. This is so when the filler is fabric, kraft, or floc.

Theory of Energy Absorption. It has been established that the energy absorbed by a specimen is only a part of that applied by the impact hammer. A reasonable assumption is that the remainder is lost by absorption in the impact machine. The system comprising the machine and specimen may then be compared to two elastic springs and the energy absorption should follow a certain pattern. An ideal system is illustrated in Fig. 5

[a] Calculated absorption based on BM-021 as explained in text.
[b] Applied energy varied from 0.098 to 0.39 ft-lb, and velocity of impact from 2.5 to 5 fps.
[c] Velocity of impact varied from 7 to 11.3 fps, except that it was 3 to 4 fps from BM-262.
[d] This is the only material broken in Table 4 that exhibits any ductility near fracture. A gage outside the region, near the clamp, of high strain will not reflect this slight ductility so that the energy absorption is low.

in which a falling weight (the pendulum) drops onto a pan attached to the springs representing the machine and the specimen. An analysis can be made on the following assumptions: (*a*) No damping in any components; (*b*) no loss of energy from the system, e.g., through the machine spring to the rigid foundation to which it is attached; (*c*) both springs weightless and elastic; (*d*) displacement of the springs during impact is small compared with the height of fall of the weight.

At any time during impact the force P, exerted by the falling weight is the same for each spring, and with spring deflections y_M and y_S and spring constants K_M and K_S is given as

$$P = K_M y_M = K_S y_S = K(y_M + y_S) \quad [7]$$

where K = spring constant for total system.

When the strain in the specimen reaches a maximum all the energy U_0, of the pendulum is given up to the springs, i.e.

$$U_0 = U_S + U_M = {}^1/_2 K_M y_M'^2 + {}^1/_2 K_S y_S'^2 = {}^1/_2 K\,(y_M' + y_S')^2 \quad [8]$$

where the primes denote maximum deflections. This is true for nonfracture, and for fracture where end effects are eliminated. Therefore from Equations [8] and [7]

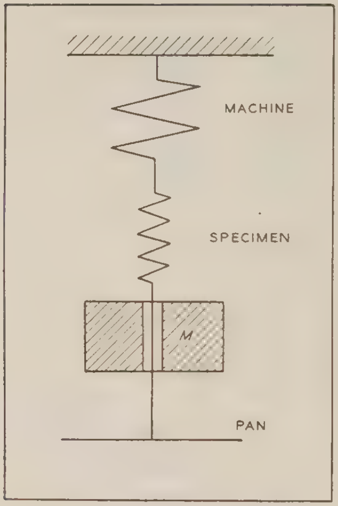

Fig. 5 Ideal Impact System

$$\frac{U_S}{U_0} = \frac{K_S y_S'^2}{K\,[y'_M + y'_S]^2} = \frac{K_S}{K} \cdot \frac{K^2}{K_S^2} = \frac{K}{K_S} \quad [9]$$

Now from Equation [7] also

$$K = \frac{K_S K_M}{K_M + K_S}$$

and on substitution in Equation [9]

$$\frac{U_S}{U_0} = \frac{K_M}{K_M + K_S} \quad [10]$$

Note that U_S/U_0 is the ratio of the energy absorbed by the specimen to that applied by the hammer.

By definition, the spring constant of the specimen K_S is equal to P/y_S and for the beam (Charpy) type of specimen the ratio is given by Equation [1]

$$y_S = \frac{PL^3}{4Ebh^3}\left(1 + \frac{3h^2}{L^2}\right) \quad [1]$$

or

$$K_S = \frac{P}{y_S} = \frac{4Ebh^3}{L^3\left(1 + 3\,\frac{h^2}{L^2}\right)} \quad [11]$$

The formula for K_S for the Izod specimen is similar so that

$$K_S = \frac{Ebh^3}{4L^3\left(1 + \frac{h^2}{L^2}\right)} \quad [12]$$

Now let these equations be applied in practice. For the Charpy machine $U_S/U_0 = 0.36$ for BM-021 when $L = 2^1/_{16}$ in., $b = 0.50$ in., $h = 0.50$ in., $E = 1.25 \times 10^6$. Hence K_S for BM-021 in this instance is 3.01×10^4 lb per in.; K_M can then be calculated from Equation [11] as 1.69×10^4 lb per in.

With these facts it is possible to predict the absorption that will be exhibited by any other bar of any dimensions and modulus and at any span. The procedure is to calculate K_S from Equation [11] and then compute the absorption U_S/U_0, from the relationship.

$$\frac{U_S}{U_0} = \frac{1.69 \times 10^4}{1.69 \times 10^4 + K_S}$$

Table 3 illustrates a fair agreement between calculated and measured absorptions. The correlation is poorest with the materials of higher modulus, BM-262 and cast iron.

With the Izod machine $U_S/U_0 = 0.26$ for BM-021 unnotched having $b = 0.50$ in., $h = 0.50$ in., $E = 1.25 \times 10^6$ psi, $L = 0.866$ in. K_S calculated from Equation [12] is 2.26×10^4 lb per in., so that K_M from Equation [10] is 0.80×10^4 lb per in. The energy absorption can be predicted in a manner already outlined for the Charpy machine. There is generally a wider difference between the actual and the predicted values than in the Charpy machine, especially when the specimen constant K_S, is high (BM-262, steel and cast iron) or low ($^1/_2 \times {}^1/_4$-in. materials).

The analogy of the system to two springs emphasizes that the low energy absorption is not some mysterious attribute of impact testing but arises simply because the machine constant K_M, is too small. Low energy absorption can equally well be observed in a flexural test but the usual testing machine is massive enough to make energy absorption practically 100 per cent.

The results for steel and cast iron are good only for small impact loadings in the elastic range, and the figures are no criterion of tests carried to ductile yielding or to failure. From the spring analogy one might conclude that in the ductile region the energy absorption would be nearly 100 per cent because there the specimen constant K_S, is low in keeping with the effective "modulus" in the ductile range.

Impact Energy Versus Span in a Drop-Weight Machine. From Equation [10] the energy of the falling weight U_0 is

$$U_0 = U_S\left(1 + \frac{K_S}{K_M}\right) \quad [10]$$

When U_0 is just sufficient to break the specimen at a given strain ϵ, the energy U_S, taken by the specimen, is

$$U_S = \frac{1}{216}\,bhLE\,\epsilon^2\left(1 + 3\,\frac{h^2}{L^2}\right) \quad [5]$$

and as

$$K_S = \frac{4Ebh^3}{L^3\left(1 + 3\,\frac{h^2}{L^2}\right)} \quad [11]$$

$$U_0 = \frac{1}{216}\,bhLE\,\epsilon^2\left(1 + 3\,\frac{h^2}{L^2}\right)\left[1 + \frac{4Ebh^3}{L^3K_M\left(1 + 3\,\frac{h^2}{L^2}\right)}\right] \quad [13]$$

If the breaking strain ϵ, is considered constant it is easy to demonstrate that a plot of U_0 versus span L goes through a minimum either by plotting values or differentiating a simplified expression with $h^2/L^2 = 0$. In the latter instance the span-depth ratio at the minimum L/h is

$$\frac{L}{h} = \sqrt[3]{\frac{Eb}{K_M}} \quad [14]$$

The effect of the depth of specimen h on the location of the minimum is elegantly illustrated by Fig. 6. For span-depth ratios higher than the minimum value the energy absorption soon reaches 100 per cent, as required by Equations [10] and [11], and the dynamic curve becomes a straight line. The absorption for the static curve is, of course, always close to 100 per cent.

In its linear region the dynamic curve lies well above the static,

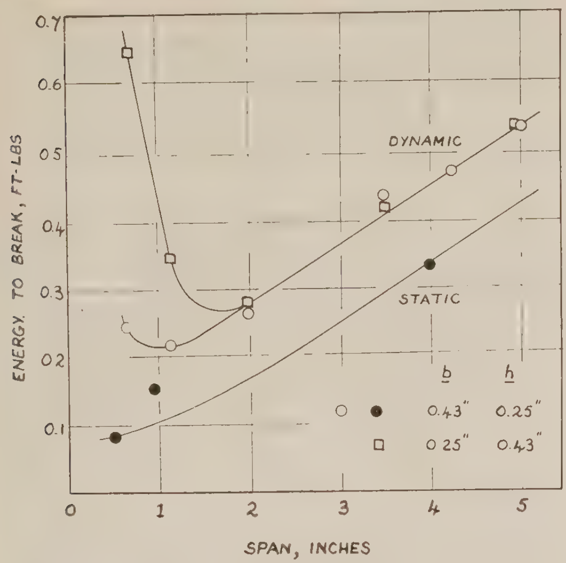

Fig. 6 Effect of Span on Energy to Break for BM-13080
(Dynamic test in drop-weight machine; static test in Amsler 60,000-lb testing machine.)

suggesting that the breaking stress is considerably elevated in impact loading. Measurement of dynamic strain in the drop-weight machine did not confirm this suggestion. In fact dynamic and static breaking stresses were equal and the energy absorption reached not 100 per cent but only a steady 70 per cent. Presumably the loss is in damping in the rather "dead" concrete base.

The existence of damping losses distorts this analogy of the impact system to two elastic springs but probably not too seriously if such losses remain constant with span.

Further Conclusions From Spring Analogy. The connection between displacement y, and time t, for the two springs is described by

$$M\frac{d^2y}{dt^2} + Ky = 0 \quad [15]$$

the solution of which is

$$y = A \sin\sqrt{\frac{K}{M}}\cdot t + B \cos\sqrt{\frac{K}{M}}\cdot t \quad [16]$$

Time of impact t_1, from the moment the pendulum strikes the specimen until the moment at which it leaves the specimen on the rebound for a blow insufficient to fracture is, from Equation [16]

$$t_1 = \pi\sqrt{\frac{M}{K}} \quad [17]$$

This time, as required by Equation [17] and established by experiment, is independent of the velocity and energy of impact provided that the specimen does not fracture. When the Izod hammer weighs 1 lb and $K_S = 2.26 \times 10^4$ lb per in. (BM-021, $b = 0.5$ in., $h = 0.5$ in., $E = 1.25 \times 10^6$ psi) and K_M (Izod) $= 0.80 \times 10^4$ lb per in.

$K = K_SK_M/(K_S + K_M)$ (from Equation [7]) $= 0.59 \times 10^4$ lb per in.

Hence $t_1 = 2.1$ millisec.

Strain-time photographs establish a mean for t_1 of 1.7 millisec for BM-021 and similar materials like BM-1914 and BM-13080. Fig. 7 shows sample photographs. The strain-time curves are often of a faintly saw-tooth outline, showing that the hammer momentarily loses contact with the specimen, which then starts to return to the initial undeformed position until the hammer overtakes it again. The slight oscillations dying away, in Fig. 7,

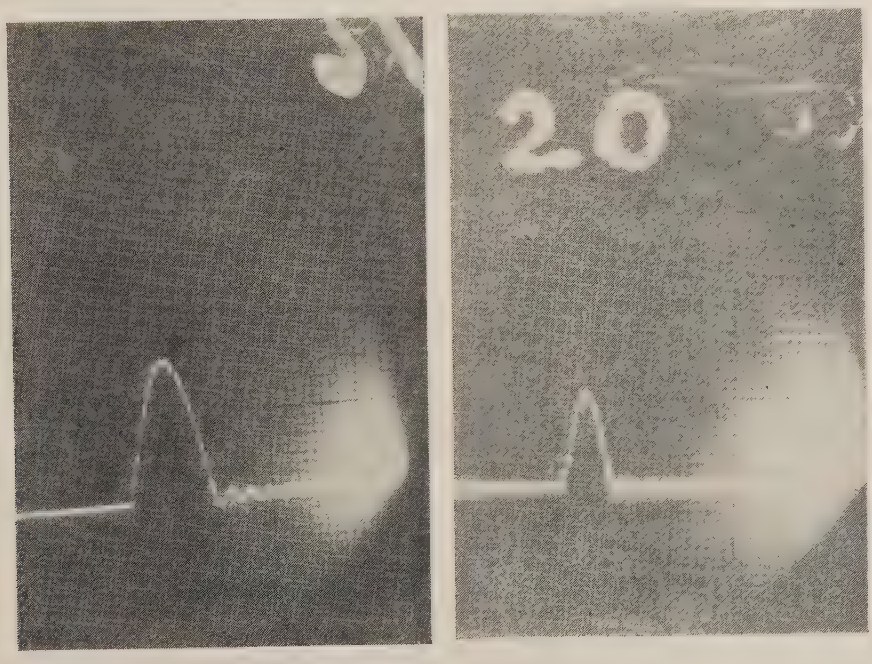

Fig. 7 Strain-Time Relations for Nonfracture Impact in Izod Machine
(BM-13080, left, $1/2 \times 1/2$ in. notched, and cast iron, right, $3/8 \times 3/8$ in. unnotched.)

arise because after the hammer has rebounded the specimen continues to vibrate feebly at its natural frequency.

When impact is violent enough to cause fracture the time of impact evidently must fall as the velocity of the striker is raised more and more. This is confirmed by photographs which resemble Fig. 7 except that the trace breaks off when the peak is reached.

When the limiting conditions: $t = 0$, $y = 0$, $dy/dx = v_0$ are applied to Equation [16] to evaluate the constants, it becomes

$$y = v_0\sqrt{\frac{M}{K}}\sin\sqrt{\frac{K}{M}}\cdot t \qquad [18]$$

The maximum value of y is when

$$\sin\sqrt{K/M}\,t = 1 \text{ or } \sqrt{K/M}\,t = \pi/2$$

then

$$y = v_0\sqrt{\frac{M}{K}} \qquad [19]$$

The force P_0 at this point is given by

$$P_0 = Ky = v_0\sqrt{MK} = v_0 M\frac{\pi}{t_1} \qquad [20]$$

where t_1 is the time of total nonfracture impact. Fig. 8 demonstrates that P_0 is linear in $1/t_1$; P_0 was calculated from readings of strain by the orthodox formula.

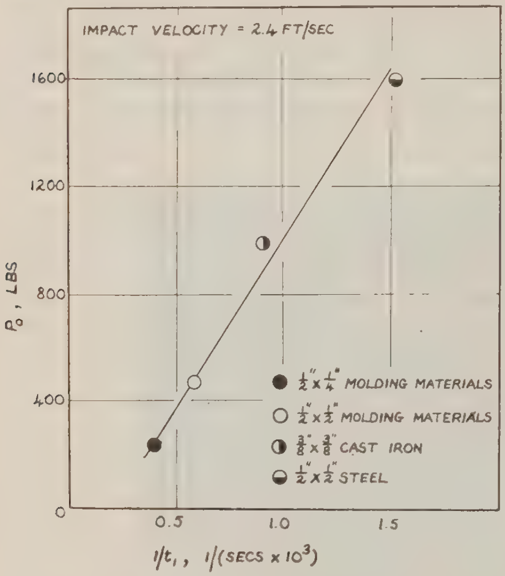

Fig. 8 Maximum Force in Pounds P_0, Developed During Impact Against Specimen as Function of Total Time of Nonfracture Impact for Constant Hammer Energy in Izod Machine

Limitations to Spring Analogy. The comparison of the impact system to two springs has allowed a successful interpretation of the experimental results in the following respects: (*a*) The effect of span, modulus, and dimensions on the per cent energy absorption in the Charpy machine; (*b*) the time of impact and its relation to maximum force; (*c*) the existence of a minimum in the curve of impact energy versus span in the drop-weight machine.

Deficiencies in the theory have appeared in the differences between results and predictions for the materials of higher modulus in both machines and for all materials in the Izod tester.

It is possible that these defects are connected with the assumption that the energy applied by the striker, divided between the specimen and the machine, is completely recovered on rebound, that is, that

$$U_0 = U_S + U_M$$

Actually this is never so with the Izod machine. The energy recovered, judged by the rebound of the pendulum, is as low as 45 per cent for a steel specimen. The energy not accounted for is probably lost by damping in the machine and its foundations. The magnitude of damping losses has already been discussed for the drop-weight machine.

The machine losses probably depend largely upon the machine itself and not too much on its attachment to a foundation, provided that the attachment is fairly rigid. It is possible that the nature of the foundation may have a marked effect on damping losses so that the Izod value indicated by the machine may depend upon its location.

Dynamic Breaking Strain. A specimen deforms into exactly the same shape as demonstrated by the distribution of strain, whether the loading is gradual or dynamic. Further, there is a close agreement between the dynamic and static moduli. So much has been proved.

In regard to breaking strain, sufficient results are not available for a final judgment. For velocities of impact up to 11 fps, it is tentatively concluded that the dynamic and static breaking strains do not differ by more than 10 per cent for the common phenolic molding materials. If this conclusion is firmly established it will follow that impact loading in the orthodox machines is, when properly analyzed, practically no different from flexural loading. This possible consequence opens up attractive vistas of simplification. The energy absorbed by the specimen in impact is incomparably more significant than the orthodox Izod and Charpy values. However, there are the objections that the end effect is not easily eliminated and the use of electronic strain equipment is undesirable for general testing. The simple alternative is to use the area under the flexural curve as the real impact energy. The flexural bar may be notched or unnotched according to the geometry of the molded object to which the results are to be applied.

The use of flexural energy brings out a very important point which has been concealed by the false results of the Izod test. Most common molding materials possess nearly the same linear load-deflection curve in flexure with nearly equal values of modulus of elasticity and of flexural strength. The unnotched impact strength is then almost constant. When there is a notch the impact strength is decided by the notch sensitivity, which is a measure of the ability of a material to withstand the weakening effect of stress concentration. Here the materials begin to show a wide range of real impact strength simply because notch sensitivity varies so much with the filler used (16).

Consequently, the "high-impact" materials, which have high Izod values, are of special value only when the molded object contains sharp notches or their equivalents; and their superiority over other molding materials almost vanishes when notches are eliminated by careful design and when they are not formed during service.

From considerations of notch sensitivity, the standard notched-bar impact tests, faulty as they are, have a much greater power of differentiating between molding materials than the orthodox tensile and flexural tests for which the specimen is not notched.

The effect of not only a notch but of modulus of elasticity, flexural strength, and ductility on resistance to impact is brought out clearly by the use of flexural energy.

Conclusions

The following conclusions are based on molded thermosetting plastics and certain thermoplastics:

Stress-Strain Diagram. The static and dynamic stress-strain diagrams are essentially identical, differing primarily only in the magnitude of breaking stress.

Strength. The dynamic breaking stress or strength is slightly elevated over the static flexural strength by approximately 10 per cent, resulting from the very high rate of loading. This is in agreement with previous data on the rate-of-loading effect as determined by other investigators.

Modulus of Elasticity. No perceptible variation in the modulus of elasticity is encountered under dynamic stressing compared with static loading.

Energy Distribution. In the static flexural test the energy absorption by the specimen is virtually 100 per cent. In the standard impact tests the energy absorption by the specimen varies from 10 to 50 per cent of the indicated energy loss of the pendulum. The remainder of the energy is lost in the machine and in kinetic energy of the broken parts of the specimen.

Notch Sensitivity. The ability of the standard notched-bar impact tests to differentiate between materials of like tensile- and flexural-strength properties is primarily due to the large variation in notch sensitivity in these materials.

Static Flexural Test. Static-flexural-test techniques employed to evaluate the energy of fracture and notch sensitivity for molded thermosetting plastics are concluded to be sufficient for predicting the service characteristics of such materials under both static and impact loading.

Theory. The theoretical concepts developed are not restricted to the testing of plastics but may be applied to the testing of metals and all other materials of construction.

Appendix

Izod and Charpy Energies at Low Swings. When the pendulum is released from a lower point than that for which the machine is calibrated, the energy is deduced from the scale reading (position to which pointer is carried by pendulum) for a free swing without any specimen in the vise. For example, for a 2-ft-lb machine having a velocity of impact of 11.3 fps:

Free swing, usual position, pointer carried = 0.060 ft-lb
Above repeated, pointer carried from 0.060 = 0.032
Therefore windage correction, full swing = 0.032
Windage correction, half-swing = 0.016
From lowered position, free swing, pointer carried = 1.381

For this reading after a specimen broke, correction to be subtracted is 0.036, according to calibration by manufacturer.

It can be shown, then, that energy at impact for free swing of 1.381 is

$$1.984 - 1.381 + 0.036 = 0.639 \text{ ft-lb}$$

$$\text{Velocity}^2 \text{ at impact} = \frac{0.639}{1.984} \times 11.3^2$$

or

Velocity = 6.4 fps

If specimen breaks when struck from lowered position and swing-through after fracture is to 1.945, then impact strength, i.e.

$$\begin{aligned}\text{Energy loss of pendulum} &= 1.945 - \text{correction for } 1.945 - (1.381 - 0.036)\\ &= 0.577 \text{ ft-lb}\end{aligned}$$

Dynamic-Strain Circuit. The entire strain circuit is illustrated in Fig. 9. Normally the measuring strain gage G is switched in, and the calibrating circuit is out. When the specimen is subjected to an impact strain the condenser allows only the voltage change to pass to the amplifier and to the oscillograph. With the strains measured, varying from 0.1 to 1 per cent, the extra amplifier A, is needed to supplement that already embodied in the oscillograph (Dumont, Model 208). The amplifier A is essentially identical to that of the second and third stages of the Y-axis amplifier of Model 208. Its chief virtue is the possession of a constant amplitude gain over a wide frequency range (60 to 10,000 cycles per sec).

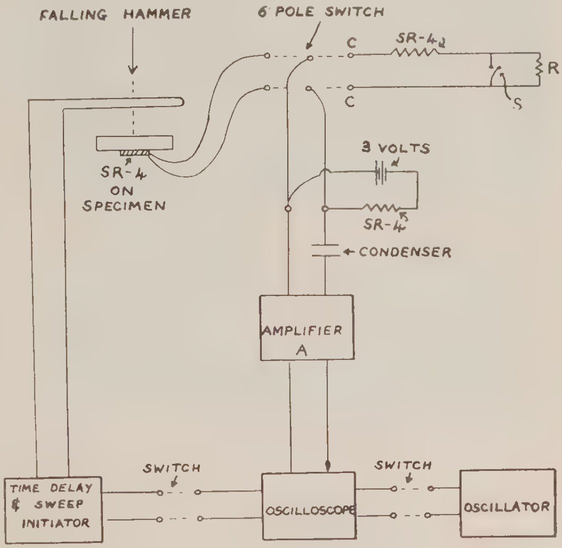

Fig. 9 Dynamic-Strain Circuit

When dynamic strain only is to be measured, the basic circuit, alone, comprising gages, amplifier, and oscillograph, is used. The oscillograph beam is narrowed to a spot, and the displacement on impact is estimated by eye. The screen is calibrated frequently by switching out the measuring gage and bringing in the calibrating circuit. When the microswitch S (normally closed), is opened by hand, an additional small resistance R is suddenly introduced and displaces the spot of the oscillograph. The value of this resistance R in terms of strain is determined as the difference in two readings when the calibrating circuit is attached to an SR-4 strain meter with the microswitch held steady closed and steady open.

Two additional circuits are added when strain-time relations are to be established, i.e., the oscillator circuit and the time-delay and sweep-initiating circuit. The latter device operates in the following fashion:

Initially the spot is off the screen. During its fall the hammer breaks a circuit which, after an adjusted time delay, causes the spot to sweep across the screen at a known rate. The sweep is in the center of the screen when the hammer striking the specimen superimposes a vertical strain displacement on the horizontal travel. The result is a record of the type shown in Fig. 7. The single horizontal sweep across the screen is secured by means of a

multivibrator circuit. With proper measures the velocity of sweep across the screen can be made constant throughout the travel. The time-delay device is a modified multivibrator in which one of the plate-grid connections is purely resistive. The tube containing this plate becomes nonconducting when the circuit receives a pulse on being broken by the falling hammer. Conduction through this tube to the sweep initiator is not re-established until there is a leak of charge from the grid to ground. The rate of leak can be varied by changing the capacity of the capacitive grid-plate connection.

After the strain-time relations are determined the oscillator circuit is brought in to determine the sweep rate. A sinusoidal vibration of 1000 cycles per sec is superimposed on the sweep across the screen so that a photograph gives a calibration of the horizontal axis in terms of time. The oscillator is of the resistance-capacity tuned feedback type.

When natural frequencies of vibration were being measured the external sweep initiator was eliminated and replaced by the built-in sweep circuit of the Dumont oscilloscope. This allowed a record of the type shown in Fig. 1 when the specimen was struck, and a calibration of the X-axis in terms of time when the oscillator was brought in.

Acknowledgment

Several of our colleagues in the Bakelite Corporation assisted and encouraged this work. Dr. C. E. Staff, Assistant Superintendent of Research at Bloomfield, and Mr. V. E. Meharg, Superintendent of the Development Laboratories at Bound Brook, were responsible for securing conditions favorable to its completion and publication. Mr. Walter Miller and Mr. Lloyd Wartman, Research Engineers at Bloomfield, loaned the equipment which they had designed for dynamic-strain measurements. Mr. W. A. Zinzow, Chief Physicist at Bloomfield, made available his staff, Mrs. J. Cairns and Mrs. R. Van Nest, for carrying out many of the experiments and calculations.

Data From Activity-Recording Instruments Applied to Textile Machinery

By C. S. PARSONS,[1] NEW BEDFORD, MASS.

The author advocates the adoption of activity recorders in the analysis of production machinery operations widely throughout the textile industry, as a means of achieving improved performance and lowered costs. After describing the several types of equipment and their applications to the study of textile-machine operations, the paper explains the procedure followed in analyzing the data recorded.

Use of Machinery-Activity Recorders

THE textile industry in general has not recognized the advantages of obtaining graphically data regarding machinery operations. There are four explanations for this as follows:

1 Low costs of labor and machinery compared with other industries.

2 In general, many productive units per machine operator.

3 Much engineering has been done by consultants, and the installation of this equipment for limited observations is expensive.

4 Nature of the machine does not readily lend itself to adapting the instruments.

With increased manufacturing costs, the use of machine-activity recorders becomes of much greater importance than formerly.

Wages have risen to new peaks and reduced costs must be realized through the more efficient use of manpower. Prices for machinery are also higher today, due not only to the increased cost of building the equipment but also because of the higher speeds, resulting in the necessity for better machining and closer tolerances.

The description which follows will show methods for analysis of machinery operations that will assist in reducing production costs.

Examples of Application

The use of recorders in studying weaving will serve as an illustration for this discussion. However, for mills that are not primarily interested in weaving, three of many other possible applications will be mentioned:

1 For cloth-finishing processes, the analysis of operation time will serve as a record of machinery utilization, as well as uniformity of cycle times for control of quality.

2 Another example of an indirect installation is that of the standard makes of regain controls, Fig. 1, which record the moisture remaining in the yarn after drying. When the sizing machine is stopped the instrument registers zero. As a result, data are available for the frequency of machine stops, time lost by the machine at the beginning of the work day, cleaning, or other reasons. In this operation the machine investment and wages for labor are comparatively high and the machinery efficiency is low due to fixed setup times.

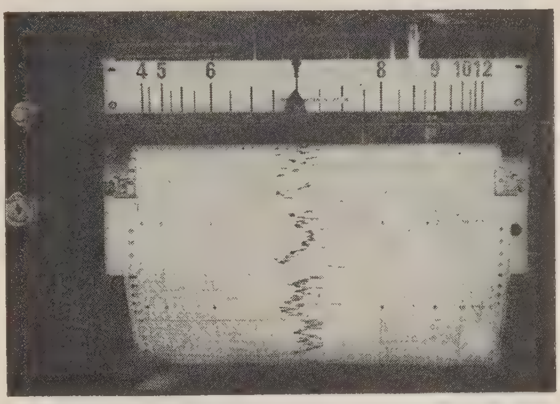

Fig. 1 Type of Regain Controller

3 Roving frames serve as an interesting example since many mills are installing new long-draft machinery to reduce the number of operations. The greatest causes of lost efficiency are end breakage, doffing, and creeling. In conjunction with conventional time studies, graphic recorders assist in the analysis of roving-frame operations for frequency of occurrence and time spent by the operator on the machine, as well as the time that the frame is not receiving the attention of the operator. This last down time includes the time when more than one of the tender's frames are stopped simultaneously.

Description of Recorders

Recording wattmeters, Fig. 2, may be used for obtaining data on one or more machines according to the electrical drive. However, their use is somewhat limited due to variable conditions in a group of machines and interpretation of average data.

Before considering the advantages of the use of instruments for loom studies, a brief description will be given of the design of recorders that are intended for machine activity only.

There are two common types of recorders and their selection will depend on the following factors:

(*a*) Permanency of the installation of the machine or instrument.

(*b*) Flexibility for use on other machines.

(*c*) Accuracy with which charts can be read.

(*d*) Ease in comparison of records from various machines to be studied.

(*e*) Availability of charts during study.

(*f*) Original cost of recorders per machine to be studied.

(*g*) Installation cost of instruments.

(*h*) Maintenance costs of charts.

For simplicity, the two types for looms will be identified as mechanical and electrical.

The mechanical type is clamped or bolted to the loom and any mechanical motion that will move or swing the pendulum located within the device will also move the stylus and make a record on the chart. In use, the recorder case is closed so that

Contributed by the Textile Division and presented at the Annual Meeting, New York, N. Y., Nov. 26–29, 1945, of The American Society of Mechanical Engineers.

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors and not those of the Society.

the stylus marks the chart only during the time when the pendulum is put in motion by the working activity of the machinery to which the recorder has been attached. The circular charts used on this device are 4 in. or 6 in. diam and are designed for 1, 3, or 7-day operation.

The electrical type (Fig. 3 for example) is manufactured by at least two different companies. It is beyond the present purposes to make comparisons of the differences in design. The following description will be limited, therefore, to one maker's design, Fig. 4. This particular instrument is built for blocks of twenty machines and records their production on a continuous running chart with the records of each machine spaced about $^1/_4$ in. apart. The electrical type may have a mechanical clock mechanism, but the operation of the machine is transmitted to the recorder by means of an electrical switch connected to the shipper mechanism or photronic equipment.

When the productive machine is in operation an electromagnet raises the pen about 0.1 in. above the base line. When the machine is stopped, the electric current stops and the pen returns to its normal position. The chart is fed through the machine so that previously printed horizontal lines spaced 0.1 in. apart normally designate 1 or 2 min according to the type selected.

Application to a Loom

On a loom with an electrical stop motion the current is shut off when the loom stops. This switch is then used for operating the

Fig. 2 Model A.W. Switchboard Graphic Instrument

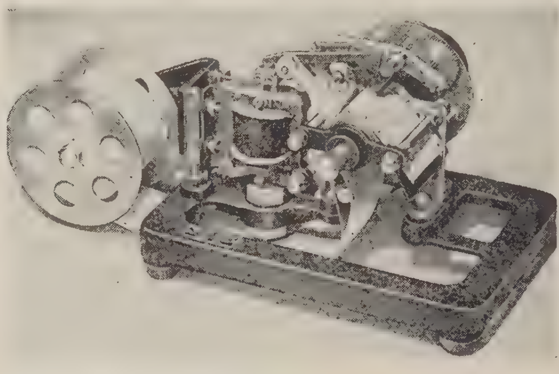

Fig. 3 One Type of Electrical Recorder

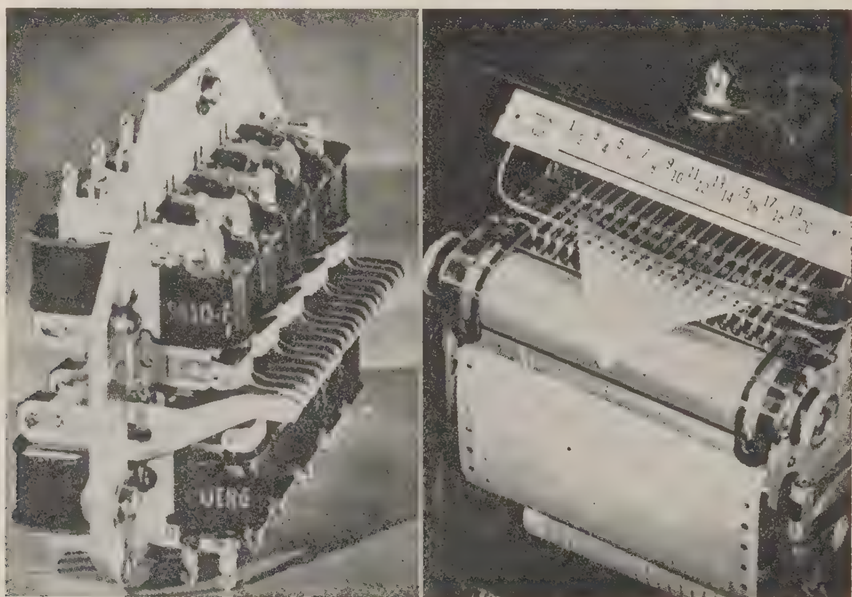

Fig. 4 Twenty-Pen Machine-Activity Recorder

(All of the electromagnets of a twenty-pen operation recorder are mounted on a single plate, but each is removable as a unit. Tilting the scale plate automatically lifts all twenty pens of the operation recorder to allow easy threading of the chart.)

pen of the recorder for indicating the stoppage for all causes. However, it is possible to cut into the wiring of the electrical stop motion and indicate on another pen the warp stoppage. A device could be arranged so that the filling-detector mechanism would actuate a third pen. Thus on one third the number of looms as might be otherwise studied, an analysis could be made of total stoppage, filling and warp stoppage, and by deduction, all other causes. The records would then conform with current practice of observing three major classifications of loom stoppage.

Explanation of Chart

One of the first impressions obtained in observing a chart such as Fig. 5, is the great variation from loom to loom even on the same cloth construction. This is readily apparent to those who are not acquainted with time-study analysis. The activity of the looms is more effectively shown by graphs than by figures, as is true of graphic presentation of such data.

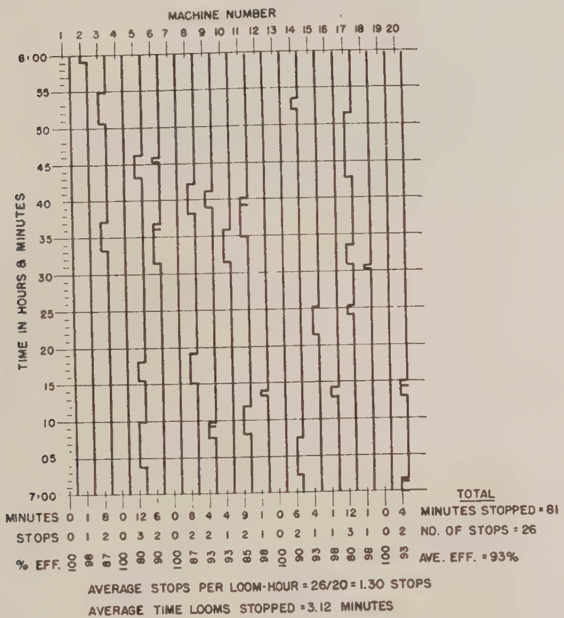

Fig. 5 Chart Made From Data Obtained With Electrical Recorder

Some engineers record operations in the sequence of their occurrence, which requires considerable clerical work in the summation of the data to follow the activity of any one particular machine. In contrast, some time-study observers record their findings directly according to the machine, irrespective of actual sequence. As a result, in a 4-hr study, considerable trouble may occur in a brief period, for example, in $^1/_2$ hr, and for the remaining seven eighths or $3^1/_2$ hr of the test the performance might be normal. Such instances are clearly seen by the use of graphic recorders.

Further examination of Fig. 5 shows that the machine numbers are across the line on the top of the page. One hour has been taken to illustrate this chart. There are 60 horizontal lines with 12 heavy lines representing 5-min intervals, as shown on the extreme left-hand margin. It will be seen that loom No. 3 was stopped for 4 min from 7:33 to 7:37.

Beneath the chart are the total stops for each loom for the hour and the total number of minutes stopped.

The efficiency of each loom can be readily calculated from the minutes of lost production.

By adding across each minute line, as shown in the right-hand column, data may be obtained on the number of looms stopped during each minute.

This twenty-pen machine-activity recorder, Fig. 4, makes graphic records of the production of twenty machines at one time. By suitable electrical connections to the starting or knockoff mechanism of the machine it is possible to determine the following:

1 Number of stops.
2 Duration of stops.
3 Frequency of stops for any period.
4 The number of machines stopped at any given period.
5 The amount of down time for that period.

This machine will give a graphical record of the quantitative analysis of the production and, if customary time studies are made in conjunction with it, there should be an accurate analysis which could not be obtained by other means. It is recognized that a complete analysis of any problem should contain quantitative and qualitative studies. For the work in textile mills the cause of machine stoppage is of secondary importance if the frequency can be accurately obtained, since if there is not a large amount of machine stoppage, the causes are not of great importance. Frequently it may be necessary to make a special analysis of the production of the machinery in order to determine the cause of machinery being stopped. This device will not give an accurate unit time that the operator spends in starting the machine in all cases, inasmuch as the machine will be stopped automatically in most cases and as a result, the down time of the machine will include:

(*a*) Time spent by the operator arriving at the machine.
(*b*) Time spent by the operator working to get the machine in operation.
(*c*) Actually starting the machine.

In most cases, such as weaving, the last two factors are very closely related and for most practical purposes can be combined.

Weekly Variations Per Machine

In order to determine the operation of one style a chart has been made from data obtained with the electrical recorder. In Fig. 6 is shown the analysis of the stops per loom-hour from ten looms operating 81 hr in 1 week. Loom No. 11 had an average of 3.04 stops per loom per hr, and an efficiency of 77.1 per cent. Loom No. 17 showed much less stoppage and operated at 90 per cent efficiency.

The test was operated for only 5 hr on the first shift Monday, 8 hr on the second shift that day. On Tuesday the results of 7 and 8-hr shifts are shown. It is interesting to observe that loom No. 12 operated at more nearly normal efficiency and although it ran poorly Thursday morning, it ran well the last of the week.

Variations Per Machine

Fig. 7 shows a probability curve of the variation in stops per hour. From this graph it is apparent that 21 per cent of the stops per loom per hour will be the average for the total test. Likewise, $7^1/_2$ per cent will vary approximately 30 per cent below or above the average and 10 per cent of the stoppage will be approximately 25 per cent higher or lower than average.

Similar data were obtained and analyzed for an entirely different cloth construction. In this case 32 per cent of the stoppages were average instead of 21 per cent. Approximately 8 per cent of the recorded stoppages varied 30 per cent above or below the mean.

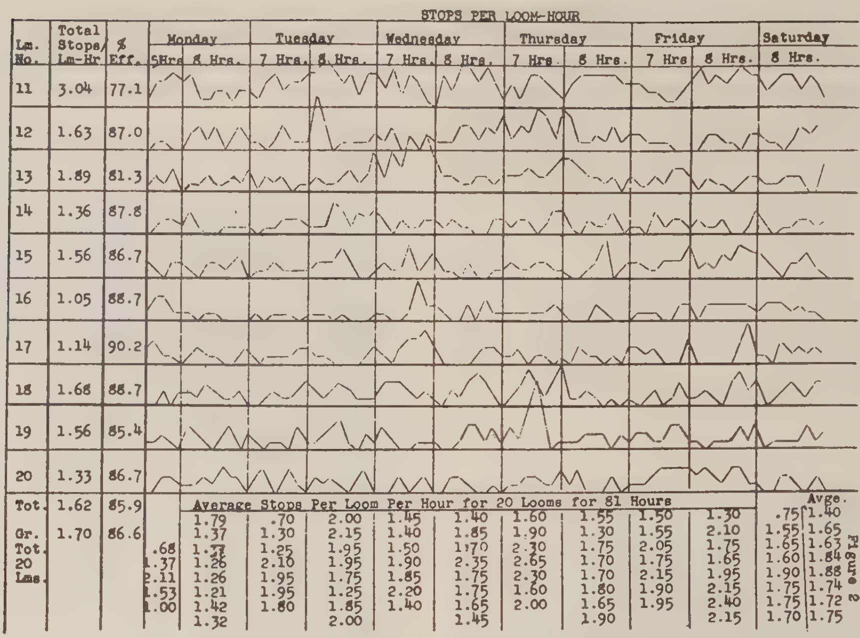

Fig. 6 Stops per Loom per Hour for Each Day

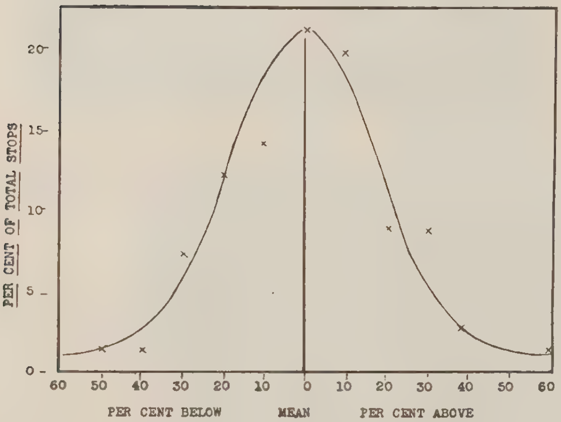

Fig. 7 Variation in Stops per Loom per Hour
(Average 20 looms; continuous testing for 81 hr.)

These data are of interest in selecting a representative test when conventional time studies are made.

Stops Per Hour Versus Unit Times

Fig. 8 shows the relationship between stops per loom-hour and weaving efficiency from a 50-hr study of twenty looms. Unfortunately, this relationship is not always recognized and the values do not closely correspond since (1) the elemental time values will vary according to the nature of the stop, and (2) the weaver is not always immediately available to start the loom.

Stops Per Weaver and Production Efficiency

If the recording instruments are to be used for weavers' work assignment, it will be interesting to examine Fig. 9, an analysis of stops per weaver per hour. In the upper half of this chart is

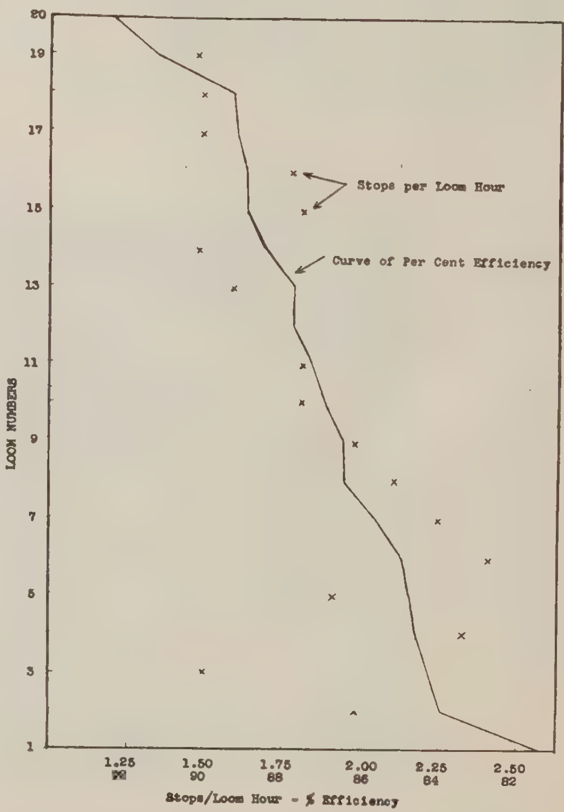

Fig. 8 Graph Showing Relation of Per Cent Efficiency to Stops per Loom per Hr

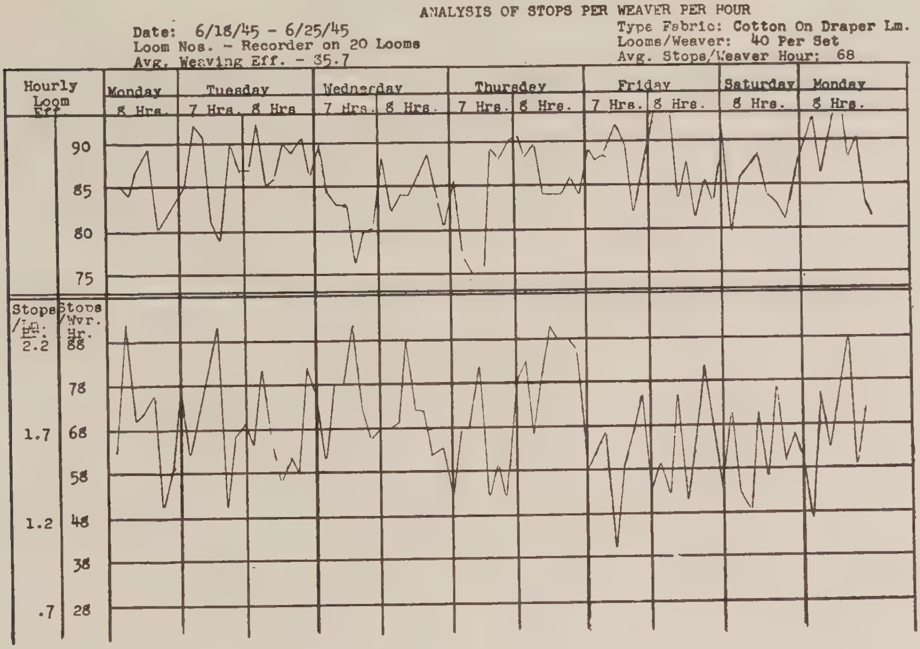

FIG. 9 ANALYSIS OF STOPS PER WEAVER PER HR

the hourly fluctuation in weaving efficiency of twenty looms for two shifts operating one week.

In the lower half of this figure is the variation in stops per loom-hour. The best shift performance was on the first shift Friday. No third shift was in operation and yet the looms ran well the first hour in spite of their being stopped. It is apparent that a test for only a few hours on one day probably would not give representative data.

Machine Interference

Published material on time studies contains very little regarding the problems resulting from multiple machine jobs. As was previously mentioned, the number of looms stopped at one time is a limiting factor of machine efficiency. An automatic loom has stop motions which operate when a yarn breaks or certain mechanical parts are not in correct adjustment. When all looms are in operation the weavers' duties are limited to inspection and a few minor tasks. Therefore the measurement of the amount of time when a varying number of looms are stopped is of great importance. To obtain these data by personal observation is difficult when a large number of looms is tended by one weaver. However, the electrical recorder makes an ideal record which not only makes the data easily obtainable but also shows graphically when abnormally poor conditions occur.

Interference Time

Interference time, as previously mentioned, occurs when more than one machine is stopped and the operator is able to work on only one machine at a time. For example, assume an operator is assigned four machines; at certain periods all machines may be running; then one stops, and he works on that machine. Then a second machine may stop before the other machine has been put back in operation and interference time occurs. The amount of lost time for this reason will depend on the following:

1 The machine setup time.
2 Number of machines per operator.
3 Average time to start one machine.
4 Frequency with which the machine stops.
5 The number of other employees that may assist in the operation of the same machines and the amount of their time.

In order to measure interference time, formulas have been set up by several engineers, but as yet there is none that has been generally accepted. This is unquestionably due to the difficulty in obtaining the data for proving the formulas. The present purpose is to show that with the use of activity recorders the desired information can be readily obtained, and that unless sufficient data are accumulated, erroneous deductions may result. In order to appreciate the importance of interference time it should be mentioned that in a recent weavers' arbitration an allowance in earnings of $7^1/_2$ per cent was claimed.

Example of Interference

An actual example of loom-stoppage tests to illustrate the importance of the problem is given in Fig. 10. Conventional time studies were made simultaneously with the activity recorder during 4-hr periods. Two of these tests were chosen showing the effect of the weaver on the production. In the case of weaver A, 88 per cent efficiency was obtained, and weaver B, working on the same job on the second shift, obtained 95 per cent efficiency. Each of the first four curves represents one hour's work of weaver A.

These graphical records analyze the number of looms stopped at $^1/_2$-min intervals. In the top curve, for instance, it is seen that at the start of the test all looms were running; $^1/_2$ min later one was stopped; and at the end of 1 min three were stopped. Four looms had stopped in the first $1^1/_2$ min of the test. At the end of 5 min all looms were again in operation. After 35 min all looms were running for approximately 5 min.

It is apparent that the four lower curves representing weaver B show much better weaving efficiency, since there is less area enclosed by the curves above the base line.

The summary of these tests is shown in Fig. 11. These illustrate that when weaver A ran the looms for 26.5 per cent of the

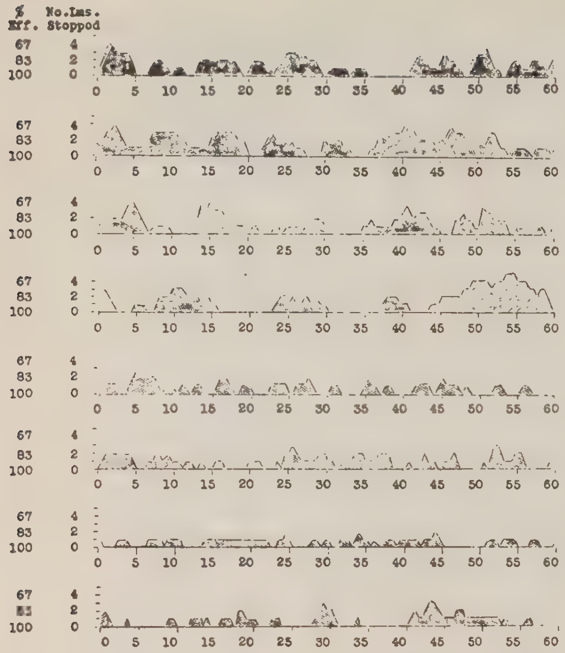

Fig. 10 Analysis of Looms Stopped and Weaving Efficiencies
(Results of eight 1-hr tests. Observations made at 1/2-min intervals.)

480 observations, no loom was stopped, and 28.3 per cent of this time one loom was stopped. In contrast, weaver B with the higher efficiency, had all looms in operation 48.1 per cent of the time, and only one loom stopped 40 per cent of the time.

It is believed that these data can be used as a basis for determining certain qualifications of the weaver, such as skill, effort, etc.

It should be emphasized that the number of looms stopped at one time does not necessarily indicate the running qualities of the job, but how the job was operated. The data below Fig. 11 are significant, namely, 7 per cent less production, 40 per cent greater unit time, resulting in much greater time lost and the looms not in operation. The interference time in the first case is 5.2 per cent and 1.2 per cent as shown for weaver B.

The number of looms that should be assigned to a weaver is governed by the frequency of loom stoppage and time spent working on such duties. In addition there must be adequate allowances for patroling the job, miscellaneous tasks, and personal time. The patrol and inspection time frequently established is 20 per cent of the total weaver's time. Modern quality-control methods establish statistical procedures for analyzing the frequency of inspection. Today less inspection is required in many instances than was formerly practiced. It therefore becomes of greater importance to demonstrate that other work is not required of the weaver. The methods just described will prove that there is not an excessive number of looms stopped requiring work by the weaver.

Conventional time studies show the amount of time the operator is not occupied performing his regular weaving duties to keep his machines in operation. When it is found that additional work can be performed, the total available time may be divided by the number of such time-study readings to obtain an average unit time available for other work. This elemental time used in conjunction with data regarding the average number of machines stopped at one time, may be of assistance in establishing the correct work assignment.

The data obtained from this recording device accumulate so quickly that the need for modern statistical analysis of test data soon becomes apparent. By means of such analysis standard deviation of data can be obtained. In addition, the adequacy of test observations can be calculated. This will unquestionably result in establishing new standards for the length of time that observations are necessary. Frequently, substantial savings in the cost of time-study observations will result.

Conclusions

It is apparent that the following information is readily available from the charts:

1 Frequency of stoppage per hour or any other desired period.

2 Duration of time for each stoppage.

3 Machine efficiency of any recorded unit or machines for any time period of the test.

4 Comparison of performance of similar machines.

5 Comparison of the performance with similar products.

6 A number of machines in one operator's job can be recorded at one time on one sheet.

7 Variation in operations:

(*a*) per shift.

(*b*) comparison of shifts.

(*c*) comparison of performance on different days or even greater periods.

8 Starting and stopping time of shift.

9 Instantaneous records for immediate investigation.

10 After installation, continuous records at minimum expense.

Other data were accumulated for further analysis which frequently are not easily obtainable, such as the following:

	Weaver A	Weaver B
Weaving Efficiency	88	95
Stops per Producing Loom Hour	2.4	2.1
Average Time per Stop in Minutes	.98	.70
Per Cent of 4 Hours Weaver Spent on Stops	54%	29%
Interference Time (Waiting for Weaver)	5.2%	1.2%
Average Number of Looms Stopped When Weaver was Available	1.1	.34

Fig. 11 Interference Time

1 Weekly variations per machine.
2 Variations for similar machines.
3 Stops per operator and production efficiency.
4 Machine interference.

Adoption of activity recorders in the analysis of production machinery operations will result in improved performance, which will automatically reduce costs. The data obtained from these instruments will serve for work-load assignments based on adequate evidence of frequencies of occurrence.

Discussion

N. M. Mitchell.[2] The paper obviously has as its objective the pointing out of benefits which may be obtained through intelligent use of recording instruments.

The author discusses his activities in connection with the use of the Esterline-Angus unit which has proved so useful to him in his own mill-engineering work. He obviously recognizes that the data which can be collected by means of this equipment can be misleading and actually dangerous if used either after insufficient testing to cover truly representative periods, or without due consideration of the practical elements, such as types of operatives, types of fabrics, conditions of machinery, and surrounding conditions.

The crying need in the textile industry today from an engineering standpoint is the determination of the true value of interferences of all types in direct-labor operating activities. The type of instruments described by the author comes more nearly to providing a means for the correct determination of interference than any equipment which has been presented for consideration to date. The fact that the type of equipment referred to is costly and somewhat cumbersome should not deter engineers from purchasing and using it, because its improvement and ultimate meeting of the real need for the industry can come only through reasonably wide distribution and use by engineers in the various mills.

There is definite need that the engineering profession recognize the fact that publication of information collected in a casual manner can be of far more damage to a mill than would be the case if the subject were to be left untouched. The use of recording instruments in connection with work-load studies or machine studies will unquestionably expand and become general throughout the field, providing its early use is not abused, or the information reported as a result of its use is not based upon incomplete or short-period testing.

This paper, covering as it does the use of recording instruments, furnishes a great deal of valuable background information. It is interesting to note the state of operational affairs from the standpoint of loom stoppage, recorded in the chart Fig. 5. This indicates that the loom stoppages at given intervals throughout the study ranged from zero to four. It would be extremely difficult to establish this fact without this type of recording instrument. Analysis of this information can serve as a means of evaluating interference and its influence on a weaver or operative of any type of multiple-machine operations. Without accurate means of measuring consecutive and respective stoppages in machinery in multiple-load activities, it would be extremely difficult to evaluate interference and properly analyze the situation.

The writer believes there is great need to devote intensive study to work-load interference in order to prevent the subject becoming one of mystery and possible misuse in respect to establishing work loads and piece rates in the textile industry. There is a possibility that the subject may have a harmful psychological influence on mill operatives unless it is treated intelligently and resolved into matter-of-fact common-sense usage by mill management.

The use of recording instruments will unquestionably bring about the revelation of substandard mechanical conditions which otherwise might pass unnoticed if these conditions had to depend only on observations of work-load students, without the use of a means for multiple coverage of a job.

Present-day labor-management conditions make it necessary to establish accurate true facts relative to all phases of machine operations as well as that for the human being. The writer is of the strong opinion that the equipment described in the paper and used along the lines obviously applied in the collection of the information which was submitted, is very much worth while and its use should be encouraged if possible in all mills.

A. Palmer.[3] Many mills are faced with problems relating to work assignment that can be solved only by scientific methods. In many cases time studies and loom-stoppage studies are satisfactory. In others they are not, either because they are resented by the employees or because they do not give the kind of information that is needed.

We have been asked by mills recently how loom-stoppage data can be obtained without taking time studies. Our reply has been to refer them to this paper.

As the author points out, the time-study data that many of us have been taking show the average performance of a set of looms. Unless we analyze the data very carefully, we have no knowledge of the performance of each individual loom. The recording instruments used by the author give him not only the average picture, but also a clear one of the performance of each individual machine.

Is it possible to use these recording instruments to show the causes for loom stoppage? If these instruments can be connected to differentiate warp breaks, filling breaks, and miscellaneous stoppages from each other, some very desirable information can be obtained.

One problem that, in so far as the writer knows, no one has been able to solve satisfactorily is the question of loom interference. Years ago Mr. McElroy and various others tried to set up work-assignment formulas that took this element into consideration. They did exceptionally well with the information that they had at their disposal, but they will probably agree, at least in some measure, with the writer's feeling that there still is work to be done in this connection by someone who is familiar with higher mathematics, particularly with the theory of probability.

In this connection it seems to me that from the records taken by instruments such as the one the author has been using, much essential basic data could be obtained. Put into the proper hands, these figures should enable someone who knows how to supply the necessary mathematical theory to develop a formula that would be useful, at least in the case covered by the particular records that were used

Much work of this nature has been done by Dr. Thornton C. Fry of the Bell Telephone Laboratories. He has supplied some of the mathematical procedures developed for the use of the telephone companies to the problem of assigning work loads in industry. To the layman his computations appear to be very complicated, not only because of the fundamental mathematical processes, but also because of the large number of variables that he includes.

In our opinion, Dr. Fry could help the textile industry if that industry supplied him with data similar to that which has been accumulated by the author. It is believed also that if the textile industry indicated to Dr. Fry that a simplified process was re-

[2] President, Barnes Textile Associates, Inc., Boston, Mass. Mem. A.S.M.E.

[3] Vice-President, Crompton & Knowles Loom Works. Worcester, Mass.

quired, he might be able to give us a sufficiently complete answer. If we know the average length of time during which looms stop; if we know the frequency of the occurrences and any other data that are pertinent to the loom-stoppage question, isn't it enough to determine what the best number of machines per operative is to keep the operator fully occupied but not overburdened, and to give the maximum production per loom?

If the writer understands Dr. Fry's work, he has included many considerations such as the weavers' wages, overhead expenses, and items of that nature, all of which are necessary but which seem to complicate the problem at the outset. If we can find out, on the basis of the loom-stoppage data, the number of looms that an operator should run to give the maximum production per loom, then the cost items automatically take care of themselves. It is therefore the writer's suggestion that as soon as the author, Mr. McElroy, and others who are doing this work, have sufficient data, they consult Dr. Fry to see what he can do with them.

A. N. Sheldon.[4] The advantages accruing from the information provided by the use of activity-recording instruments seems quite obvious from the paper. The utility of its general adoption would appear to justify the cost if the data derived therefrom become the basis of a careful and continuing analysis; the records are accurate, impersonal, visual, and permanent, for guidance of both management and operatives.

There is one deduction that appears possible from the data in Fig. 5, and that is that for this particular example there were too many looms per weaver; out of 20 looms there were only 5, (looms 1, 4, 7, 13, and 19) that operated continuously throughout the hour covered by the record, and the remaining 15 looms stopped 26 times and were unproductive for a total of 81 min. Consequently the efficiency of these 15 looms was only 90 per cent; the stops per loom per hour were 1.7, and the average duration of each stop was 5.4 min. Expressed in another way, out of these 20 looms, 1.30 looms were stopped for the entire hour. For a group of 1000 looms this is equivalent to 65 looms continuously idle, if the record for 1 hr is typical of all other hours. Since the capital invested in a single loom might be $1500 (including the cost of loom, building, air conditioning, power and light wiring, heating, etc.) there would be approximately over $100,000 of invested capital totally and always unproductive.

Fig. 5 also shows that there were only 12 min in the hour, or 20 per cent of the time, when all 20 looms were running simultaneously, which together with the average duration of stoppage of 5.4 min per loom, is strong circumstantial evidence that the weaver's job for this particular situation was too extended, with consequent loss in production from the looms and unproductive effort by the weaver.

Whether or not the foregoing conclusion is correct, the activity recorder presents a reliable device for investigating its validity, and as indicated by the chart in Fig. 5, there is nothing gained by increasing the looms per weaver beyond the point where loss of production, arising from "interference time" becomes the dominant factor. Incidentally, it does not seem consistent to penalize the loom-operative efficiency with interference time just because the weaver is not present to run it.

Discussion

In 1945, when there was a ban on national meetings, some papers originally scheduled for these meetings were presented before local groups. In the case of these papers the Committee on publications suspended its rule, which requires simultaneous publication of paper and discussion, and accepted discussion based on the published paper.

Heat Transfer in the Locomotive Boiler[1]

F. P. Huston.[2] The author presents in this paper a procedure for determining the output of any given quality of steam from conventional locomotive boilers for given rates of heat release and gas production.

The first part of the computation deals with the transfer of heat through radiation to the firebox and combustion surfaces. The second part deals with the transfer by convection through the walls of the tubes, flues, and superheater pipes. The author shows that the results of the computations are in reasonably close agreement with test data.

The variations between the maximum evaporation estimated by present methods and the maximum obtained on test, as reported by the late C. A. Brandt,[3] on ten locomotives range from 47 per cent more evaporation obtained on test over the estimated maximum to 14 per cent less. This wide spread is apparently due to the rule-of-thumb methods now in use, as exemplified by the 55-lb rule, dating back to 1912, as the result of the "Coatesville tests," or Baldwin's 80-lb rule. Either of these figures will apply at some low to moderate firing rate, but many locomotives are used today at near the maximum steaming capacity where the evaporation from the firebox surfaces may approach a rate of 125 lb of water per sq ft per hr.

The author, in presenting the formulas derived from the generally accepted fourth-power equation for the transfer by radiation in the firebox and the double logarithmic equation for transfer by convection in the flues, provides a means to compute the expected performance of the present-day conventional boiler to greater accuracy and enables a better proportioning to be made between the firebox and the flue areas. His contribution should prove of great value in studying the influences of changes which obviously must be made in the combustion of the fuel and features of design to enable steam-locomotive boilers to meet the requirements imposed by the modern trend toward higher steam pressures, greater demands, higher superheat temperatures, and better fuel economy.

H. S. Vincent.[4] In the opinion of the writer the author's Fig. 5 would be more useful had it been constructed to show the temperature of the combustion gases at the rear flue sheet instead of a mythical equilibrium temperature. With such data the heat absorbed through the walls of the firebox would be given by the expression

$$H_a - H_t = h_f \quad [1]$$

where

H_a = available heat of combustion
H_t = heat in gases at rear tube sheet
h_f = heat absorbed through walls of firebox.

The use of the author's Equation [1] for radiation from combustion gases cannot be defended, as has been shown conclusively by Schack (1),[5] Hottel (2), and other investigators. Equation [1] of the paper can apply only to radiation from solid fuel where the total radiations are normal to the cold surface. To give correct results the equation must include a factor allowing for the average angle through which the radiating surface "sees" the absorbing surface. Hottel (3) has given data for evaluating such a factor in cubical furnaces as well as in other types of heat exchangers. In so far as the writer is aware nothing of this character has been worked out for the locomotive furnace.

About 10 years ago the writer published a series of articles (4) on the general subject of heat transfer in the locomotive boiler with the particular purpose of determining the proportion of available heat taken up by its various components, viz., firebox, tubes, and superheater. The data there given were derived from 62 laboratory tests of nine different types of locomotive boilers. The method used in determining heat transfer through the walls of the firebox is given by the writer's Equation [1]. The principal chance of error in using this method is from excess air introduced through the fire door or above the fire. With automatic-stoker-firing, this contingency does not often arise.

It will be observed from the author's Fig. 3, especially in the series C, that there is excessive fluctuation in the measured temperature of the gases in the firebox in relation to the rate of firing. The reason for this abnormal variation in recorded temperature is that only one temperature determination is made for each complete test whereas for the temperature in the smokebox, as well as for all other data, frequent determinations are made. In any calculation based upon the firebox temperature it is evident that the results will be more logical and accurate if a mean of the observed firebox temperatures is taken rather than those actually recorded. This was the method pursued by the writer in the articles referred to.

The author has given as criteria his Table 4 and Fig. 5, for estimating the heat transfer through the firebox walls for any given locomotive. Using these data, the writer has prepared Table 1 of this discussion, for the locomotive series C, for which the author includes four tests. The writer's Table 1 includes eleven tests of this locomotive, only two of which coincide with tests cited by the author.

The data for columns 4 and 5 of Table 1 are taken from the articles cited and are based upon the Fry (5) method of calculating these quantities. Column 6 gives the equilibrium temperatures, as established from the author's Fig. 5, although they do not agree with those shown in his Table 3, column 4. Column 7 of Table 1 is the so-called "radiation factor," taken from the author's Table 4, at the appropriate temperature. Column 8 of Table 1 gives the heat absorbed through the firebox walls in per

NOTE: Dcf = dry coal fired; sfg = square feet of grate area; hs = heating surface.

cent of the heat available for absorption, using the author's method of calculation. Column 9 gives data similar to those of column 8, but calculated in accordance with the writer's Equation [1]. Column 10 shows the difference in percentage between columns 8 and 9. This varies from about 3 to 13 per cent and indicates to the writer that firebox absorption, as determined by the author's formulations, is too low by this amount.

In the present state of the art it seems inadvisable to attempt to show the exact method by which the available heat reaches the firebox walls. This determination must await the patient work of investigators who are equipped to take all of the complex elements of the problem into consideration. A very great need today is for many more laboratory tests of the locomotive with the results made available to all who can use them. It seems most fitting that such tests should be made under the auspices of the Federal Government and could well be conducted by the Bureau of Standards. It can be said without contradiction that our present knowledge of the thermodynamics of the steam locomotive is largely due to the generosity of the Pennsylvania Railroad in making available records of tests conducted at their plant in Altoona.

5 "A Study of the Locomotive Boiler," by L. H. Fry, Simmons-Boardman Publishing Corporation, New York, N. Y., 1924.

C. J. SURDY.[6] In more recent years the so-called "80 lb rule" has been quite generally used by locomotive builders in calculating the evaporative values of the boiler direct-heating surfaces. The presence of these new and higher values has been mentioned by both Johnson and Brandt but Mr. Fry in his paper has clearly and pointedly attributed this to high rates of combustion. Table 3 (columns 3 and 6) of the paper offers abundant proof of the existence of a 55 lb-125 lb evaporative range per sq ft of direct heating surface, depending upon combustion rates.

The present work may be viewed as an extension of the author's treatise "A Study of the Locomotive Boiler" (Simmons-Boardman Publishing Corporation, New York, N. Y., 1924) in which tables 5, 9, 10, 11, 12, 13, and 14 show exhaustive test results forming the original premise of the conclusions set forth there and expanded in the present paper. In this earlier treatise the steam produced at the various rates of combustion is equated in terms of the total heating surface of the locomotive firebox. However, it is clear from this study and the present paper that a definite relationship exists between rate of combustion and evaporation per square foot of heating surface.

To locomotive design engineers this paper presents an authoritative exposition of the factors which make the modern high-capacity steam locomotive possible. The author should be complimented for this further contribution to his studies of the locomotive boiler.

AUTHOR'S CLOSURE

The author appreciates the comments made by Messrs. Surdy and Huston.

Mr. Vincent's discussion contains several points of interest. The author welcomes comparison between the present paper and Mr. Vincent's extensive and valuable study of heat transfer in locomotive boilers (4) published in 1935 which deserves to be better known. Mr. Vincent took the results obtained in nine series of locomotive tests and by noting the rate of heat release in the firebox, the weight of the gases of combustion, and the temperature at which they left the firebox, he computed the rate at which heat was taken up in the firebox. From this the total heat taken up by the boiler could be separated with considerable precision into its three components, heat absorbed in firebox, heat absorbed in flues and tubes, and heat absorbed in superheater. In his discussion of the present paper, Mr. Vincent points out that his values for heat taken up in the firebox are higher than those given in the paper. This is true and further consideration of the problem leads to the conclusion that a modification should be made of the statement in the paper that "radiation at the equilibrium temperature corresponds to the heat actually taken up by the firebox." Some correction should be made for the fact that the equilibrium temperature is higher than the temperature at which the gases leave the firebox. Mr. Vincent's figures, which confirm some of the author's earlier figures (5), show that the heat actually taken up by the firebox is larger than that computed as radiated by Equation [1] of the paper by about 12 per cent at low rates and by about 5 per cent at high rates of operation.

It might be possible to arrange a corrective formula to give better correlation between rate of heat transfer in the firebox and the radiation at the equilibrium temperature. It is however not highly important to determine the exact rate of heat transfer in the smokebox. Radiation at the equilibrium temperature gives a reasonably good qualitative picture of the distribution of heat absorption between the firebox and the flue bundle, and for the present attention is directed to the fact that the method as a whole gives a remarkably exact procedure for estimating the over-all output of locomotive boiler. Mr. Vincent in a private

communication says that he has made a number of checks of the method and has found no case in which it deviates from the measured results by more than one per cent.

Rather than strive for too high a degree of idealistic perfection, the author prefers, as stated in the preamble of the paper, to work with an admittedly empiric method that produces useful practical results.

NOTE: Computed equilibrium temperature for Test 527 Series C should be 2120 not 2320.

Rate of Temperature Change in Short-Length Round Timbers[1]

MAX JAKOB.[2] In the paper under discussion one finds sentences like the following: "Each curve....was prepared by plotting the temperatures for each heating period for the logs of different diameters." These logs are not logarithms, but real logs. Unfit for mathematical treatment as they may seem to be, the paper subjects them to such treatment. It contains and illustrates the solution of the differential equation for simultaneous axial and radial thermal conduction in short cylindrical pieces of timber which are suddenly heated and then kept at constant temperature all over the surface.

Strange enough, almost the same solution as needed and used here in conditioning timber logs was previously needed and derived for a similar practical purpose, namely, glass cooling, by Williamson and Adams.[3] The author's solution also includes the case of different thermal conductivities in axial and radial directions as occurs in timbers; this, however, causes only a slight change in the main equation.

The paper contains a great number of useful graphs, representing the temperature distribution in logs, 4 and 8 ft long, of different diameters for different time intervals. These graphs can easily be converted to be used under different conditions.

Two items in this very valuable paper are to be regretted: The author does not use the letter symbols for heat flow as recommended by the American Standards Association.[4] The American Standards symbol for thermal diffusivity, for instance, is α. The author, however, uses h^2 and q^2 for the diffusivities in the radial and axial direction, respectively, which is particularly undesirable because the American Standards employ h for surface coefficient of heat transfer and q for heat-flow rate. For time the author uses T which the Standards reserve for temperature on absolute scale as generally adopted.

The other objection is that the author, though knowing very well that diffusivity is a property of the substance in which conduction occurs, proceeds as though it were different for heating the timber in steam or water. His statement, "The diffusivity values determined from experimental tests may be considered as values which apply for the heating medium used," is likely to confuse readers who are not quite familiar with the concept of "diffusivity." It is significant that the author speaks of a "diffusivity factor for radial heating" instead of, "diffusivity factor for radial direction." What he actually has in mind is that the surface coefficient which we call h, is generally greater for condensing steam than for water in contact with the surface, and that increasing h accelerates the propagation of temperature in a solid as does an increase of the diffusivity α. The effect of an increase of h may therefore be approximated by raising the value of α. Then, however, one should call this an "apparent" or "equivalent" diffusivity and express it by a different symbol, for instance, α_e. Both lines in the author's Fig. 1 obviously represent equivalent rather than true diffusivities, since the author neglects the temperature difference between the heating medium and the surface of the timber samples.

Temperature-Time Distribution in Rectangular Bars[1]

G. M. DUSINBERRE.[2] The authors suggest the use of their curves in the calculation of cooling rates during quenching of steel. There are two difficulties here, as follows:

The first lies in the way the results are plotted, log of the temperature-change ratio against a function involving time directly. This is a widely used convention. It has the advantage, in plotting, that the lower end of each curve approaches a straight line. However, this region will ordinarily be of little interest. The authors wisely give a better chart in the same space by omitting values of T_x less than 0.02, which values are shown on many similar charts.

Consider the cooling of steel from 1600 F to 100 F. The most important changes occur around 1300 F, or $T_x = 0.8$. The logarithmic plotting constricts this part of the chart. Therefore a uniform scale of T_x would be an improvement. A further improvement would be to use $\sqrt{a\theta/w}$ as abscissa to expand the time scale in the region of practical importance.

The second difficulty lies in the use of constant values of the thermal properties (k, c_p, and h) and neglect of the latent heat of phase change. These simplifications are unavoidable under the conventional mathematical treatment, although not under a numerical treatment.

Take an experimental temperature-time curve for a steel slab or billet. There is a definite "flat" in the critical range not shown on curves such as the authors'. If, by choice of mean values of the properties, we attempt to fit a theoretical curve to this, we will find that it must be in error, perhaps 10 to 15 per cent in position at some point and even more in regard to slope. This makes any question of two- or three-figure "accuracy" rather academic.

The fact is that calculus is not adequate for this problem. If we have to get solutions by calculation rather than experiment, then the writer feels that we should use the less esthetic but more accurate finite-step methods.

AUTHORS' CLOSURE

The authors appreciate Commander Dusinberre's amplifying statements regarding the mathematical method of solution. The log plot for T_x function has become a generally adopted method of plotting this type of data. The authors realize that it is sometimes desirable to plot the results in a different way from the one they chose; hence they have included the tabular results shown in Tables 1 through 5, which may be used in plotting the curves in any desired manner.

This method of solution involving the solution of the partial

[1] By W. M. Rohsenow, M. A. Aronstein, and A. C. Frank, published in the February, 1946, issue of Trans. A.S.M.E., vol. 68, pp. 135–141.

[2] Department of Mechanical Engineering, Virginia Polytechnic Institute, Blacksburg, Va. Mem. A.S.M.E.

differential equation is limited to cases in which the thermal properties (k, Cp, and h) are essentially constant and in which there are no phase changes and no latent heat. This method may be applied to the steel slab mentioned by Commander Dusinberre provided the temperature range does not include the critical point.

Measurements of Temperatures in Metal Cutting[1]

K. J. Trigger.[2] The authors present interesting results of average chip temperatures versus cutting speed, Fig. 2 of their paper. The reasoning for the observed constancy of chip temperature at the higher range of speeds appears logical. The results do, however, emphasize the desirability of determining the temperature at the tool-chip interface, or contacting surface, since, as pointed out, this is where tool failure has its inception.

The most direct approach to the tool-chip interface temperature is probably by means of the tool-work thermocouple, which is, in reality, composed of many thermocouples in parallel so that the emf measured is the average emf of all the points of contact (thermocouples) of the tool and chip. A temperature so determined represents therefore the average temperature at the tool-chip interface, and in this discussion is referred to as the cutting temperature. The writer has been investigating cutting temperatures utilizing the tool-work thermocouple principle and using a steel-cutting grade of cemented carbide as the tool and annealed NE8640 as the workpiece.

Since the authors used carbide tools on steel it would seem that the results of the cutting-temperature tests should apply quite directly, and sample curves are submitted to supplement the authors' statements concerning the temperature of the tool.

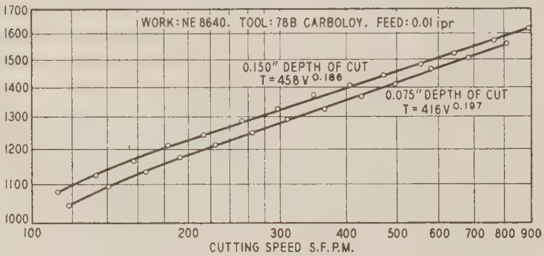

Fig. 1 Cutting Speed-Cutting Temperature Relationship

Fig. 1 of this discussion shows the effect of cutting speed upon cutting temperature for two depths of cut at constant feed. Many similar curves have been obtained, all of the same general shape.

It is generally observed that the curves droop at low speeds and/or light cuts. Examination of the chip under such conditions reveals some scuffing or roughness on the separating surface coincident with the presence of a significant built-up edge on the tool. The effect of the built-up edge would be to remove some of the thermocouples from the separating surface, and thus lower the indicated (average) emf. Supporting this belief is the fact that when the chip shows no scuffing the points lie on the straight-line portion of the curve. Such conditions have been observed in many tests to date.

Within the range of conditions herein reported, the writer believes that cutting temperature is essentially a power function of cutting speed, and is expressed by the relationship $T = CV^n$, where C is a constant and n the exponent. This contention receives support from the older and more common relationship for tool life and cutting speed, i.e., $VT^n = C$, where V = cutting speed, sfpm; T = tool life, min; C = const; and n = exponent.

Various investigators, including the authors, report constant cutting force if cutting speed is the only variable. If, then, the tool life is shortened exponentially with increased cutting speed, it is presumably due to increased temperature at the tool surface in a similar sort of relationship, that is, exponential.

Authors' Closure

Professor Trigger's comments on the paper, "Measurements of Temperatures in Metal Cutting," are very much appreciated. Professor Trigger's method of measuring the cutting temperatures between the chip and tool by using a tool-work thermocouple appears to be a logical procedure to determine the maximum temperatures developed in metal cutting. In fact, Professors Gilbert and Boston first presented a paper before the A.S.M.E. in December, 1934, entitled, "Relation Between Cutting Force Temperature and Tool Life in Cutting Steel With Single-Point Tools." The time of this presentation coincided with the depression and the paper was never published. Another paper entitled, "Cutting Temperatures Developed by Single-Point Turning Tools," was presented to the American Society for Metals[3] by Professors Gilbert and Boston. Both of these papers showed that the cutting temperature as a function of cutting speed was practically a straight line for any shape of tool, except for speeds below approximately 25 fpm, where the curve was concave downward but above the normal line. Professor Trigger's definition that the thermocouple is composed of many thermocouples in parallel is in agreement with the authors' opinion. In fact, the concave portion of the temperature-cutting speed curve for the lower speeds is presumably due to this particular principle, in that at lower speeds the built-up edge becomes larger, and actually introduces a considerable amount of worked metal between the newly formed chip and the tool face. This is one of the objections of the tool-work thermocouple. Apparently Professor Trigger's work as shown in Fig. 1 was carried out at speeds where the built-up edge did not exist or was small in size. His lowest speeds were about 120 fpm, with tool temperatures above 1000 F.

An objection to the tool-work thermocouple is the difficulty of calibration. The authors have found that the electrical properties of all tool bits are not identical, and that the calibration must be carried out between a piece of the work being cut and that particular cutting tool doing the cutting. It is also necessary to make a new calibration for each material cut. It would be interesting to know Professor Trigger's procedure in calibrating his tool-work thermocouple.

The two-tool thermocouple in which two dissimilar tool materials form the cutting edge, eliminated the need of calibrating against the material cut. The greatest trouble was in regrinding the tool, and also the sintered carbide wore faster than the other tool material at cutting speeds below 100 fpm. This two-tool thermocouple had the advantage of being able to cut any material, the emf developed between the two tools being a direct function of the temperature at the cutting edge and independent of the material cut. This permitted the use of this two-tool thermocouple to compare cutting temperatures under standard sizes of cuts when turning steel, cast iron, nonferrous metals, etc.

Later a double tool-work thermocouple was developed in which

[1] By A. O. Schmidt, O. W. Boston, and W. W. Gilbert, Trans. A.S.M.E., vol. 68, 1946, pp. 47–49.

[2] Professor of Mechanical Engineering, College of Engineering, Department of Mechanical Engineering, University of Illinois, Urbana, Ill. Mem. A.S.M.E.

[3] Trans. American Society of Metals, vol. 33, no. 3, September, 1935, pp. 703–726.

one tool of high-speed steel, and a second tool of cast nonferrous alloy, identical in shape, were used when cutting a bar at the same speed, feed, and depth of cut. The reading on the potentiometer was independent of the material being cut, the tool grinding was simplified, and the accuracy of reading was improved.

All of these types of thermocouples gave practically straight-line relationships between the cutting speed and temperature. In this respect the authors' work does not agree with Professor Trigger's, due perhaps to the fact that our temperatures are normally below 1000 F, whereas Professor Trigger's are normally above. It would therefore appear that further work on this subject to establish the relationship between the temperature and the tool life as a function of cutting speed would be well worth while.

Summary Report on the Joint E.E.I.-A.E.I.C. Investigation of Graphitization of Piping

By S. L. HOYT,[1] R. D. WILLIAMS,[2] AND A. M. HALL[3]

Following the failure in January, 1943, of a welded joint in a high-pressure steam line at the Springdale Station of the West Penn Power Company, among the several investigations undertaken, a research program was initiated at Battelle Memorial Institute to study the fundamental causes of graphitization and the restoration of graphitized joints. The present paper is a summary of the findings to date on graphitization and includes not only work of the Institute but elsewhere. It gives the present status of significant points which have emerged in relation to manufacture and fabrication.

Introduction

THE failure in January, 1943 (1)[4] of a welded joint in a high-pressure steam line at the Springdale Station of the West Penn Power Company made the whole power industry, as well as the metallurgical world, acutely aware, for the first time, that graphite could form in steel piping operating at steam temperatures, and that its presence in certain instances could so weaken the piping as to produce a service hazard.

Among the several investigations immediately begun by various interested groups was a research program at Battelle Memorial Institute under the auspices of a Joint Subcommittee on Graphitization, initiated by the Edison Electric Institute and the Association of Edison Illuminating Companies. The program was set up to study the fundamental causes of graphitization and the restoration of graphitized joints. For new pipe, it was desired to know one or more kinds of steel which would be resistant to graphitization.

In particular, interest centered about the segregated type of graphite found in the Springdale pipe. This occurred as a continuous film across the entire cross section of the pipe, at or near that zone of a welded joint which had been heated to the Ac_1 point of the steel during welding, i.e., the low-temperature edge of the weld-heat-affected zone. Instead of being plane, this film of graphite was scalloped in conformity with the heat-affected zone and in a cross section through weld and stock, showed a characteristic "eyebrow" formation. Graphite nodules might have formed elsewhere in the pipe, but with their random distribution they were thought to be relatively harmless. The segregated streaks, however, tended to form a weak and brittle plane across the entire pipe and it was imperative that their formation be prevented.

This paper is a summary of the findings to date on graphitization investigations, both at Battelle and elsewhere. These include reports by approximately 40 operating companies on the condition of their steam lines[5] and by additional investigators, principally staff members of the power companies and of suppliers who had individual points under study.

In general, no attempt is made in this paper to distinguish between the sources of the data discussed, although this has been done in the Battelle progress reports to the Joint Subcommittee.

It is intended in this summary report to give the status to date on points that have emerged as being of greatest significance in manufacture and fabrication. Fortunately, it is possible to give reasonably good answers to some of the more important questions, but it should be recognized that the exploration of a new field is likely to raise additional questions, the existence of which had not been anticipated. That is true in the present instance and is principally responsible for the tentative position which must be taken on some of the points.

Influence of Deoxidation and Alloying Elements

Aluminum Deoxidation. Among the plain-carbon steels the high-aluminum-deoxidized types (i.e., 1.5–2 lb Al per ton) were found to be relatively susceptible to graphitization at the higher steam temperatures. Plain-carbon steels, low-aluminum-deoxidized (i.e., 0.5 lb Al per ton, or less) or straight silicon-deoxidized, appear resistant to graphitization at present steam temperatures. These findings are confirmed by both plant and laboratory investigations (2). Bead-welded high-aluminum-deoxidized plain-carbon steel showed graphitization after only 500 hr at test temperatures of 925 F and 1025 F. At the same test temperatures a low-aluminum-deoxidized plain-carbon steel contained no more than possible traces of graphite after 7700 hr.

Residual aluminum in the steel, or some factor which runs parallel with it, seems to promote graphitization very strongly. In this connection there is some evidence, though it is inconclusive, to suggest that it is residual aluminum as metallic aluminum, rather than as Al_2O_3, which is effective. This point will be again considered when the relationship between graphitization and microstructure is discussed.

Molybdenum. The presence of about 0.5 per cent molybdenum in the carbon-molybdenum steel retards graphitization to some extent. However, molybdenum was originally added to improve creep strength, and its retardation of graphitization is a secondary effect, far outweighed by the action of aluminum deoxidation as an accelerator. Thus while low-aluminum-killed or straight silicon-killed carbon-molybdenum steel was found to be very resistant to graphitization, high-aluminum-killed carbon-molybdenum steel graphitized to an appreciable extent, though not as readily as high-aluminum-killed plain-carbon steel. The graphitization of carbon-molybdenum steel and the effect of aluminum deoxidation may be seen by comparing Fig. 1 with Fig. 2.

[5] Of the forty stations reporting, seven had cases of severe graphitization (chain-eyebrow-type or heavily segregated nodules), two had cases of moderately severe graphitization (segregated nodules), four had cases of moderate graphitization (random nodules), three had cases of slight graphitization (a few random nodules), and 23 had found no graphite.

Chromium. Examination of the chromium-molybdenum steels has developed a feature of the microscopic identification of graphite that deserves mention. Chromium is added, in this case, to produce a carbide of such stability that it will be immune to any tendency to form graphite at operating temperatures. There is considerable evidence to support this belief, and one expects the microscopic examination of heated test samples to show nothing of the nature of graphite. Actually, one observes very small particles, even in samples containing 1 per cent of chromium or more, and he is inclined to report "traces of graphite." One of these small particles is shown in Fig. 3. The occurrence of graphite is highly doubtful and the situation calls for positive identification of these particles, if not in the present samples in which the task would be relatively difficult, then in samples which have been heated long enough for them to grow into a more convenient size. Unfortunately, at this time it has not been possible to carry out the work necessary to complete the identification—they might be chromium oxide or some other unsuspected reaction or precipitation product.

With this in mind it is noted that chromium-molybdenum steels, even one containing as little as 0.25 per cent chromium and made with high-aluminum deoxidation, did not appear to graphitize in a laboratory test. After heating at 925 F and 1025 F for 5000 hr, careful metallographic examination showed so little graphite, if any, that it could not be identified with certainty. Under the same conditions, control specimens, similar in composition except that no chromium was added, graphitized after 2500 hr. Figs. 4 and 5 indicate these differences. Thus the stabilizing or retarding capacity of chromium is much greater than that of molybdenum, and is apparently sufficient to offset the accelerating tendency of aluminum.

Nickel. It has been reported that nickel in amounts up to 3.43 per cent does not increase the tendency of low-carbon molydenum steel toward graphitization in the temperature range of 950 F to 1050 F and may quite possibly decrease it.

Effect of Prior Heat-Treatment and Structure

Welding. The striking peculiarity in the graphitization problem confronting the power industry is the fact that when segregated graphite forms in pipe during service it usually occurs in a narrow zone in the pipe immediately adjacent to a weld. It is evident that the location of this zone and the degree of graphite segregation in it are largely determined by the thermal gradients imposed on the pipe during welding. Microscopic examination shows that this zone of graphite segregation is the narrow band through the wall of the pipe near the weld and following the weld contour, which has been heated approximately to the Ac_1 point of the steel by the welding operation. The influence of welding heat is shown in Figs. 6 and 7 for a high-aluminum-killed plain-carbon steel.

Welding is not the only factor operating to produce segregated

(Graphitization in stock unaffected by welding heat. Nital etch; ×250.)

graphite; we must not overlook the simple fact that the steel must be inherently graphitizable. Thus the thermal treatment accompanying welding is a necessary but not a sufficient condition for the production of a brittle zone of segregated graphite.

Carbide Particle Size. There is evidence to indicate that it is the structure of the carbides in the zone heated to the Ac_1 point which induces the graphite segregation. In particular, the observations suggest that a spheroidized or coarse-carbide structure, such as may obtain at the Ac_1 isotherm after welding, is especially susceptible to graphitization. Fine carbides appear to be more resistant to graphitization. This was brought out in a test of a high-aluminum-killed plain-carbon steel which was heated 1350 hr at 1025 F. Specimens water-quenched from 2000 F or 1600 F, or normalized at 1650 F, (all containing fine carbides) showed no graphite, while specimens annealed at 1400 F, or spheroidized 65 hr at 1250 F, had graphitized, forming random graphite nodules. Furthermore, welded carbon-molybdenum steel pipe, normalized at 1650 F, was also resistant to graphitization, presumably because the susceptible structure near the weld was replaced by a relatively fine and resistant structure. It is to be assumed that longer heating would ultimately produce random graphite, a point that is more adequately treated under the kinetics of graphitization.

Normality. The accumulated evidence seems to confirm the hypothesis that a steel which is structurally completely "normal" in the McQuaid-Ehn test is highly resistant, though not necessarily absolutely immune, to graphitization (2). In this light the action of aluminum as an accelerator of graphitization may be its known capacity for promoting spheroidization of car-

bides and for inducing "abnormality" in steel. Thus the influence of aluminum may actually arise from its effect on structure.

Contrariwise, the persistence of well-defined lamellar pearlite shown by Kerr and Eberle for long-continued heating of normal steels may be directly associated with freedom from graphitization (2).

Postweld Heat-Treatment. Postweld heat-treatments at 1200 F or 1300 F have shown a little less graphitization as compared to the as-welded condition. The reason for this small effect is not clear, though for molybdenum steel it has been suggested that the effect of 1300 F is due to the formation of molybdenum carbide (3). A striking effect, however, is produced by a postweld stress relief carried out slightly above the Ac_1 temperature of the steel which re-forms the structure produced by welding. In tests of a high-aluminum-deoxidized plain-carbon steel, stress-relieved at 1370 F, the formation of segregated graphite was completely prevented, although random graphitization was not prevented, and in fact may even have been accelerated.

The same steel, stress-relieved at 1290 F or less, after welding, developed segregated graphite near the Ac_1 isotherm. These tests were carried out at 925 F and 1025 F for time intervals up to 7700 hr.

It may be pointed out here that some instances of resorption of segregated graphite have been observed in test samples.

Creep Strength. One of the points immediately considered upon discovery of the apparently beneficial effects of stress-relieving above the lower critical temperature (Ac_1) was the effect of such a treatment on the creep strength of steel so treated. Creep tests could not be made in the limited time available, but samples of carbon-molybdenum steels were "stress-relieved" at 1425 F, and the microstructures thus produced were compared with those shown by Weaver (4), in his study of creep in carbon-molybdenum steel. This comparison suggested that the creep properties would most probably correspond to Weaver's specimens representing an annealed initial condition. As such, the stress-relieving treatment above the lower critical point would not be excessively harmful to the creep strength.

Influence of Stress and Strain

It is not possible at this time to distinguish very clearly between stress and strain (cold work) as factors in the graphitization problem. High-pressure steam lines are under stress in service and some evidence has been gathered to indicate that stress may accelerate graphitization and in so doing, produce a typical stress pattern. It is not considered a primary cause of graphitization, however, and the information at hand indicates that it is effective only in the case of a readily graphitizable steel.

As an example of the effect of cold work, a tensile bar of high-aluminum-deoxidized plain-carbon steel was pulled to fracture at room temperature and heated 1350 hr at 1025 F. Random graphitization was found in the bar, increasing in severity toward the fracture. A similar test in a low-aluminum-killed plain-carbon steel produced no graphite whatever. Straining by bending at room temperature slightly increased graphitization in a high-aluminum-killed plain-carbon steel, while compressive straining at 1025 F considerably increased the amount of graphitization. No relationship was found between the strain lines (Lüders' lines) produced in a steel specimen by tensile deformation and the location of graphite nodules.

The information so far accumulated points toward stress, and particularly that developed at steam-line operating temperatures, as a probable accelerator of graphitization which should not be overlooked.

Effect of Joint Preparation

Among the original questions raised by the power industry regarding the susceptibility of carbon-molybdenum steel pipe to graphitization, three dealt with the possible effect of joint preparation as a cause of graphitization. Specifically these were: (*a*) Is grease applied to the pipe end during fabrication a possible source of graphite? (*b*) Does gas-cutting of pipe ends preparatory to welding cause graphite to form? and (*c*) Does cold-working, such as produced by too coarse a tool feed in machine-beveling of pipe ends, cause graphite to form?

Tests indicate that none of these three factors is likely to contribute to the graphitization of steam lines. However, the evidence is not absolutely conclusive, particularly in regard to the effect of grease. Hence it appears advisable to adhere to the practice of cleaning all joints free from grease and other foreign matter prior to welding. It is known, of course, that perfectly clean steel graphitizes if it is of the susceptible type.

As for flame-cutting and heavy tool feeds, it is believed, in view of the depth of penetration of weld metal below the original surface of a joint, that neither of these surface preparations would cause the formation of graphite.

Kinetics of Graphitization

On the basis of preliminary work that has been done an attempt has been made to apply the principles of chemical kinetics to the problem of graphitization.

The approach consists in treating the graphitization process as a slow chemical reaction and determining its course with time at constant temperature, as given by the fraction of carbon transformed from the initial condition (carbide) to the final condition (graphite), for different intervals of time. The plot of the fraction of total carbon transformed, against time at temperature, is the reaction curve of the process. By correlating a series of reaction curves, each representing the progress of graphitization at a different temperature, the effect of temperature may be determined; at least for the temperature range over which the mechanism of the process remains the same.

Fig. 8 shows reaction curves obtained from data for the graphitization at 925 F, 1025 F, and 1125 F, of "reconditioned"[6] specimens of the original Springdale pipe, a high-aluminum-deoxidized carbon-molybdenum steel. The fraction of carbon transformed to graphite was determined by metallographic methods and plotted semilogarithmically against time. The solid portion of each curve represents the experimental data. The broken portions have been added to show the probable form of the complete curves.

For the purpose of illustration only it was decided to use these data to indicate the effect of temperature on the rate of graphitization. For this the half-life time at each of the three test temperatures was read directly from the reaction curves as the time required to convert one half the total carbon in the steel to graphite. These half-life times for 925 F, 1025 F, and 1125 F, plotted semilogarithmically against the reciprocal of the absolute temperature, yielded the approximately straight-line relationship shown in Fig. 9.

Reports on the progress of graphitization usually make use of some simple description of amounts, particle size, and distribution, with photomicrographs of typical areas. That is not adequate for quantitative treatment; and for the present work it was necessary to determine the amount of graphite in each sample. This was done by polishing several microsections of each sample and then estimating the average area covered by graphite. This figure in per cent gives the per cent by volume. Upon converting the volume per cent to weight per cent, it was necessary to apply a correction factor which was experimentally determined by a comparison of a limited number of microscopic determinations with direct chemical analyses for free carbon.

Some refinements in technique are still desirable but the data

[6] Air-cooled from 2200 F and normalized at 1650 F.

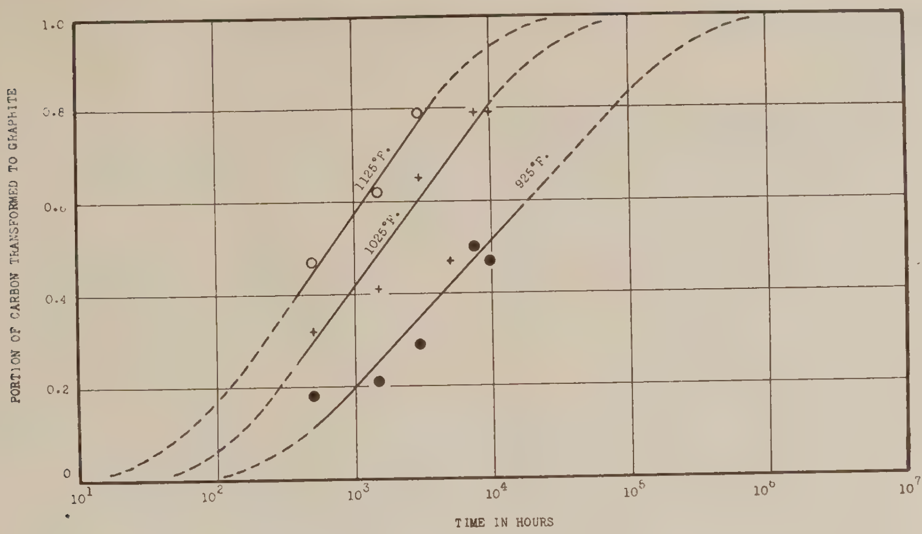

FIG. 8 REACTION CURVES FOR GRAPHITIZATION OF SPRINGDALE PIPE

presented are doubtless adequate for illustrating the principles. At this time no great accuracy can be claimed for the individual determinations. However, the data are good enough at least to suggest that the graphitization process, when it occurs, follows a definite law. Furthermore this law, whatever it may be, appears to be reasonably uniform in behavior over the range of temperature involved in the test program. Should this initial finding be corroborated by additional and more precise determinations, this is a conclusion of major significance since it gives legitimate grounds for predicting, from the findings at higher and accelerating test temperatures, what will happen at lower temperatures, or down to approximately 925 F. There is some reason to believe that at some temperature below 925 F, which would probably be different for different steels, some sort of change in the process sets in, such as one or more of the conditions for graphitization dropping out, and hence that a temperature range of immunity is entered. That temperature, if adequately determined and defined, would then become the maximum safe operating temperature for the steel in question.

While this preliminary study was conducted for the primary purpose of checking the soundness of the use of accelerating test temperatures, in other words, checking the experimental approach to the problem, it suggests, and possibly justifies, certain speculations on the type of data or observations which are needed to give an adequate understanding of the process. That should be the ultimate goal of an experimental program which seeks the control of graphitization. Since this is speculation, the discussion will be brief.

There is some thought that graphitization is a nucleation and growth process. The characteristics of such a process are: (*a*) An incubation period of nucleation over which it appears that nothing happens; (*b*) a period of relatively rapid change with corresponding depletion in the reacting substance; and (*c*) a final slow change to the end point. The graphitization data indicate that the reaction starts relatively fast and proceeds at a decelerating rate. (The curves in Fig. 8 do not show this on account of the logarithmic scale, but it becomes clear when time is plotted on a linear scale.) At least the data are consistent with the idea that nuclei are already present in the steel used for this test, though in other graphitizable steels that might not be so and the difference should show up in the reaction curves. Of

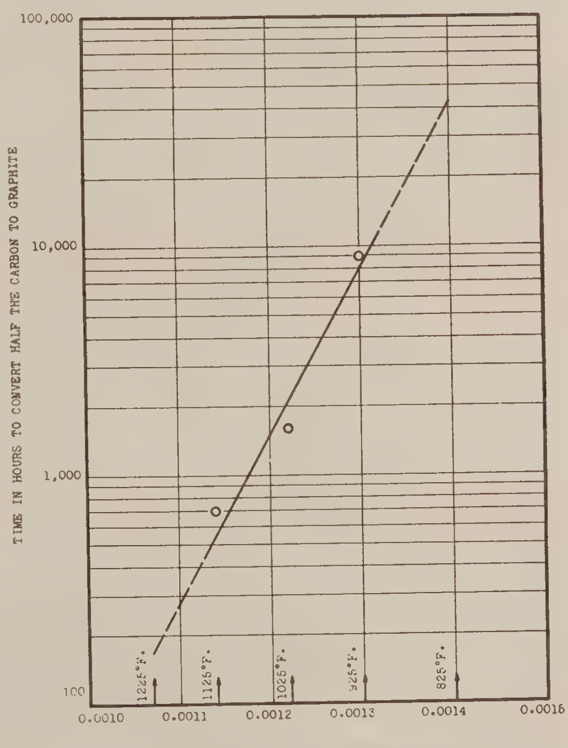

FIG. 9 EFFECT OF TEMPERATURE ON RATE OF GRAPHITIZATION PROCESS

course if the second type of steel were tested for too short a time one might erroneously conclude that it was immune.

The idea of graphite nuclei being present in some steels is not without support since Mr. Bolton of the Lunkenheimer Company has shown by chemical analysis that the Springdale steel before service contains about 0.04 per cent free carbon. Other steels

which are either immune or relatively resistant, ran about 0.01 per cent. These amounts are too small to be seen under the microscope.

An experimental verification of these points is greatly to be desired. While they may appear to be of greater theoretical than practical interest, that would probably be a shortsighted viewpoint. Laboratory tests of 10,000 hr duration are relatively long, yet an accelerated test at 1125 F, which steps up the rate thirteenfold would require over 30,000 hr to produce the effect of normal operating life at 925 F. In other words, we are required by the force of circumstances to pass judgments which are based on relatively short acquaintance with the steels in question. Obviously, the more complete our understanding of graphitization, the better able we will be to appraise steels and structures in short-time tests.

Another line of speculation which may not be without interest relates to the effect of structure, particularly the striking segregation of graphite along the Ac_1 isotherms. From thermodynamics it is known that the slope of the straight line in Fig. 9 is proportional to the energy change involved in the mechanism which controls the rate of the reaction. Calculation gives a heat value (32,900 cal per mol) which is consistent with the assumption that the controlling factor is diffusion, presumably the diffusion of carbon atoms through the ferrite matrix from the carbide source to the graphite nodules. This immediately raises the question of what carbide particles serve as sources.

In most processes of nucleation and growth it is not difficult to identify the reacting material, or source. For the case of graphitization, the malleabilization of white cast iron comes to mind, with nodules of graphite surrounded by uniform, impoverished zones. The present type of graphitization departs from this ideal picture, at least in numerous instances, in that the graphite nodules may be surrounded by carbide-containing areas. Obviously, those areas did not provide carbon for the graphite; the carbon must have come from more distant points. This seems to be just a simple statement of the facts, and if correct it shows that not all of the carbon is equally "available."

There is some evidence on availability. In the Battelle program it was found that a steel that was either quenched and drawn, or normalized, did not graphitize under test conditions which produced graphite in the same steel when it was annealed. The obvious structural difference is a fine carbide in the first two conditions and a coarse carbide in the latter. The concept of availability is sufficiently intriguing to induce one to attempt to apply it to the case of segregated graphite. Upon heating the steel to Ac_1 during welding the carbide has an opportunity to coarsen and this would probably be aided by aluminum deoxidation. If graphite nuclei are already present, graphitization would start almost immediately by drawing carbon from those carbides which were able to provide it. Even so, the process is slow and, particularly at service temperatures, some time would elapse before much visible graphite had formed. If nuclei had to form first, still more time would be required. In either case the graphite which formed at the Ac_1 isotherm preferentially would serve as a "sump" and drain carbon from coarsened carbides in the vicinity.

While this picture may be adequate for some of the cases of graphitization, a review of the findings to date indicates that it by no means covers all cases. Smith and Brambir (5) found, for example, in experiments with an end-quenched bar of graphitizable steel that the quenched end produced graphite on being heated subsequently. That seems to contradict the work at Battelle on a quenched and drawn sample, but more likely it is probably just telling a different story.

Without going into all the details, this seems to be the status of our knowledge of the graphitization process. By this we mean that from the standpoint of understanding the process, the data which have been accumulated do not fall into one simple pattern, They suggest, rather, that there are varying and multiple conditions which must be satisfied for the initiation and progress of graphitization.

Work on the kinetics of graphitization suggests that it should be valuable for distinguishing between the cases of free graphite initially present in the steel and of the spontaneous generation of nuclei. The latter condition would require a longer period for the growth of finite particles, and in the incubation period would be difficult to distinguish from the case of a nongraphitizable steel. (The determination of free graphite might make this possible.) Furthermore, it now appears that absence of graphitization at a given time interval may be due either to (*a*) absence of nuclei in an otherwise graphitizable steel, (*b*) absence of available carbon in an otherwise graphitizable steel, or (*c*) stable carbide. Conditions (*a*) and (*b*) could conceivably become modified with additional time and produce late graphitization. Condition (*c*) is the case desired for good practice, for both fabrication and service.

The ultimate use of the kinetic approach would be to make it possible to make reasonable predictions of behavior in service from accelerated test data gathered in the laboratory.

Summary

Considerable information has been gathered on the effects of several of the variables operating in the graphitization of high-pressure steam lines. Some data have been accumulated on the influence of deoxidation and the composition of the steel, on the effects of welding heat and other preservice heat-treatments, and on the influence of microstructure and cold deformation. While the results are largely qualitative, they throw some light on the mechanism of graphitization and give a basis, the only one at present, for prescribing the steel to be used and for setting safe operating temperatures.

In summarizing, it is thought that the following can be said on the points that appear now to be most important in this problem:

Deoxidation. The deoxidation practice used in making steels which are presumably of the graphitizable type is of great importance. In particular, the use of $1^1/_2$ to 2 lb of aluminum per ton is known to have a pronounced effect. This applies to both carbon and carbon-molybdenum steels of the type used for steam lines. This effect of aluminum has been found by controlled tests to be more pronounced than is the stabilizing effect of 0.5 per cent molybdenum. Steels which have been tested with not over 0.5 lb per ton and straight silicon-killed steels are relatively immune. These steels are characterized by showing a highly normal case structure in the McQuaid-Ehn test while the same steels deoxidized with the larger amount of aluminum showed the abnormal structure. While there is still some small doubt as to the absolute immunity of these normal steels, they should be regarded as highly resistant and capable of operating under more severe conditions without graphitizing than the same steels of the abnormal type. (No. = 0.001 ± per cent; Ab. = 0.020 + per cent Al).

Composition. Since carbon is the element which produces the graphite, it would seem advisable to keep it on the "low side," although no quantitative determinations have been made of the effects of different carbon contents. Chemical analysis reports a small amount of free carbon in these steels as manufactured. The indications to date are that the nongraphitizing steels contain not over 0.01 per cent free carbon and the graphitizing steels about 0.04 per cent. This lead is so important that it should be followed up. This might be done by determining free carbons on new lots of both wrought and cast steels for information purposes.

Manganese and silicon are both known to affect graphitization in general. In the present case these elements have been held at fairly constant levels and to date no specific effects of these elements have been uncovered.

Molybdenum is known to form a (metallic) carbide and has been shown to exert a stabilizing effect on pipe steels. Molybdenum also has a characteristic effect on the structure of steel and may have a secondary effect of this type. Just what this effect might be has not been worked out as yet, certainly not quantitatively.

It has been reported that heating the molybdenum steels at about 1300 F has a pronounced beneficial effect on graphitization. It was suggested that this is due to the conversion of iron carbide to the more stable molybdenum carbide, but apparently it is not known that this molybdenum carbide would remain stable at the lower operating temperatures or that the immunization is permanent.

Chromium also forms a highly stable carbide and is now thought to be the best element to add to carbon or carbon-molybdenum steels to keep them from graphitizing in service. In contrast to molybdenum, the addition of as little as 0.25 per cent chromium has at least checked graphite in high-aluminum-killed steel. While tests of chromium-containing steels have not as yet given definite or final answers, particularly on the amount of chromium which would be needed, the tests do indicate that chromium prevents or vastly retards graphitization. In this connection, however, it should be mentioned that tests of steels containing as much as 1 per cent chromium, or more, have shown "traces" of some new substance. Since one is looking for graphite in these samples, he is inclined to refer to this material as graphite since it occurs as very tiny dark specks. On the other hand, this material has not been identified, a determination which would not be without difficulties.

Welding. While random graphitization can occur in pipe steels without causing undue alarm, the heat effects of welding establish a highly critical zone where the stock has been heated to about the Ac_1 temperature. This is the major cause of segregated graphite.

While the usual stress-relieving temperatures of 1200 to 1300 F retard graphitization, it seems to be necessary to eradicate the structure of the heat-affected zone to have any important effect on the elimination of segregated graphite. Such a stress-relieving would be carried out just above the critical temperature for a long enough time to accomplish this. This treatment should be regarded as a good "corrective measure" for use with a known or suspected graphitizable steel, but by no means as a substitute for a stable steel.

Inasmuch as welding sets up the structural conditions which invite graphite segregation, welding techniques should be looked for to ameliorate this condition. The use of a high heat input and preheat which widen the heat-affected zone should be beneficial and should improve the effectivenss of stress-relieving above Ac_1.

Prior Structure. Prior structure of the part as welded does not appear to have a dominating effect on graphitization. While the point has been kept in mind by investigators, it does not appear to warrant very much attention. Even so it might have a secondary effect on the susceptible structure which is set up by welding. With this factor, as with various other factors of graphitization, an analysis of its precise effects is far less important than finding a steel which is immune to graphitization and not sensitive to deoxidation, welding, structure, etc. In particular, it is not thought that the structure set up by hot-upsetting, hot-forming, etc., is of primary importance in the graphitization problem.

Cold Work. The manufacture of pipe and castings for steam lines does not involve cold work except scarfing and similar operations. On this account the effects of cold work do not enter into the problem in a practical way, but laboratory tests have shown that cold deformation of graphitizable steels accelerates the process. On this account it might be used in a testing program to distinguish between graphitizable and nongraphitizable steels.

Service Temperatures. In view of the present interest in higher steam temperatures it is advisable to point out that the various investigational programs have all related to service temperatures not above the 925 F to 950 F mean-operating-temperature range. Steam temperatures of the order of 1000 F and above would very likely call for a different type of steel.

Suggestions for Power Industry. (*a*) For new steam-line installations it is suggested that a "normal" (low-aluminum-, or silicon-killed) carbon-molybdenum steel with initial graphite content of not more than 0.01 per cent, or a chromium-molybdenum steel containing 0.50 to 1 per cent chromium and 0.50 per cent molybdenum be used. Also, since postweld stress-relieving is general practice, it appears advisable to stress-relieve these steels above their Ac_1 temperature after welding. Future work may show this to be unnecessary.

(*b*) Though joints exhibiting some graphitization in service can generally be "healed" by normalizing at 1650–1700 F, they should be checked periodically.

(*c*) When a joint is severely graphitized, the only safe procedure is to cut it out and reweld, or replace it with a spool of new pipe. In fact, where severe graphitization is encountered in a large number of joints throughout the installation, it is safest to replace all the pipe with a type resistant to graphitization.

ACKNOWLEDGMENTS

The authors wish to express their appreciation of the advice and assistance given by the members of the Joint E.E.I.-A.E.I.C. Subcommittee on Graphitization of Piping, Messrs. Alex D. Bailey, Sabin Crocker, L. E. Hankison, and T. E. Purcell; and to thank Messrs. C. E. Sims, Francis Boulger, and J. R. Heising for their valuable contributions to this paper; and Miss Jean Kernahan for metallographic assistance.

Furthermore, the authors wish to acknowledge the data from other research investigations and operating company reports made available to the Joint Subcommittee from which they have drawn freely.

Discussion

ARTHUR MCCUTCHAN.[7] This paper is an excellent summary of

[7] Engineer, Engineering Division, The Detroit Edison Company, Detroit, Mich. Mem. A.S.M.E.

the findings both at Battelle and elsewhere. The tentative position taken in answering some of the important questions is justified by incompleteness of the findings and the different conclusions possible from the data at hand.

From a comparison of microstructures the authors have concluded that a postweld heat-treatment just above the lower critical temperature will not be excessively harmful to the creep strength. It is hoped that subsequent creep tests will support this conclusion. Examination of weld-probe samples from both high- and low-aluminum-deoxidized carbon-molybdenum welded joints after a few years' service at 900 F shows that a definitely spheroidized structure has resulted. It would seem important therefore to have creep tests and stress-rupture tests made on this spheroidized material for comparison with service creep measurements.

Efforts to reproduce the "strain-line" type of preferential graphitization apparently were not successful. The importance of understanding the cause of this type of graphitization is so great that further efforts should be made to reproduce this phenomenon under laboratory conditions.

While the structure produced by hot-upsetting may not, as stated by the authors, be of primary importance in the graphitization problem, it is the writer's opinion that the segregated type of graphite found adjacent to the welds and in the strain lines at Springdale is in some manner related to hot-upsetting.

I. A. Rohrig.[8] The data embodied in this report represent a vast amount of work and constitute a fundamental contribution that can be utilized in the selection and specification of new high-temperature-steam pipe material.

In association with graphitization, the effect on the physical strength of infected joints that are in service is of the greatest importance. In an endeavor to evaluate the effect of graphitization, two 10-in-diam welded joints in medium-carbon steel A.S.T.M. A-106 Grade B pipe that had been in service at 825 F for 59,000 and 64,000 hr, respectively, were investigated by the writer's company. Each weld joined a corrugated filler at the downstream side and a pipe bend at the upstream side. The graphitization that had occurred at these joints was judged to be "moderate" in amount and is shown in Fig. 10 of this discussion. Tensile tests made on samples taken from the joints indicate that the graphitization had no adverse effect on the tensile strength. Notched-bar tests made on samples cut from the two joints showed, however, a reduction in shock resistance in three of the four graphitized areas tested.

The results from these tests are given in Table 1 of this discussion. Samples from the same joints were laboratory-heated at temperatures that were varied between 850 and 950 F for a period of 6000 hr to develop further graphitization. Typical graphitization found in these samples after laboratory-heating is shown in Fig. 11. Since only small samples were used, notched-bar tests were not made after laboratory-heating, but bend tests made on strips cut from these laboratory-heated samples resulted in a distinct crack at one side of one weld as shown in Fig. 12. These samples were taken from welds in vertical piping, and it is interesting to note that the most severe graphitization at each weld occurred at the lower or downstream side of the weld.

The results obtained for these joints after laboratory-test-heating of samples removed from service show that although only moderate graphitization had developed as a result of 60,000 hr of service, a critical type of graphitization might possibly develop in these joints as a result of somewhat longer service.

The results presented by the authors regarding stress-relieving treatments above the lower critical temperature are of particular interest since heat-treatment within or above the critical-temperature range after welding offers a means of overcoming dangerous graphitization. A graphitization test is under way at the writer's company, using welded samples of three different heats of A.S.T.M. A-206 low-aluminum carbon-molybdenum pipe material in the normalized, and also in the hot-rolled and drawn condition. Some of the samples received a treatment of 2 hr at 1400 F, following welding. The graphitization test is being conducted using laboratory-test-heating and temperatures varying between 950 and 1150 F. The results obtained after 1500 and also after 2500 hr of test are given in Table 2 herewith. In one of the heats under test, namely, heat 10,600, the 1400 F stress-relieving treatment appears to be effective in preventing graphitization, whereas in heats 3099 and 6347 graphite was found in the samples that received the 1400 F treatment. Further study is to be made of the time-temperature relationship of various heat-treatments in that temperature range.

Each of the three heats was judged to be "normal" in the McQuaid-Ehn test. Heat 6347 had the most clearly defined normal structure and was classed "Type 1," while the other two

heats were classed as "Type 2." At the end of 2500 hr of test the least amount of graphite was found in the samples of the steel classed as having Type 1 normality.

With respect to the influence of strain in promoting graphitization, as given in the paper, the results obtained from an examination of stress-rupture samples may be of interest. Stress-rupture samples of low-carbon carbon-molybdenum, and chromium-molybdenum steel that had been tested at Purdue University in 1200 F steam, were examined for graphitization by the writer. These samples have been discussed in detail in a paper by J. T. Agnew, G. A. Hawkins, and H. L. Solberg.[9] The samples were obtained through the courtesy of Professor Solberg and were examined for the presence of possible graphitization and for determination of their response to the McQuaid-Ehn test.

Six specimens of each of the three types of steel were examined. Although each of the three steels was highly "abnormal," which indicated that graphitization might have been expected in the carbon and carbon-molybdenum samples, no clearly defined graphite was found in any of the samples. While this result is different from that reported in the paper by Dr. Hoyt, it should be remembered that the samples obtained from Professor Solberg, and here referred to, were tested at 1200 F instead of at 1025 F. The range of stresses under which the samples were tested as well as the hours of test are shown in Table 3 of this discussion. The absence of graphitization in the carbon and carbon-molybdenum samples, even though abnormal, may have been due to lowering of the Ac_1 temperature for the steels as a result of stress at the relatively high temperature of test. Because of its alloy content it is unlikely that graphitization would occur in the chromium-molybdenum samples.

In other work a probable indication of graphitization as influenced by stress was found in a failed low-carbon superheater tube. Creep failure had occurred as a longitudinal crack at the front of the tube due to overheating. It was interesting to note

that graphitization had occurred parallel to the failure and at a short distance at either side of the failure where it appeared to be localized as a result of probable critical stressing of the tube wall. Graphitization found in the tube is shown in Fig. 13 of this discussion. This is believed to be one of the few instances reported of the occurrence of graphitization in tubing smaller than 4 in. diam.

Authors' Closure

The authors appreciate Mr. McCutchan's thoughtful analysis of the present status of the graphitization situation. The determination of the creep strength of pipe steel in various structural conditions does not come within the scope of the investigation of graphitization, but they concur in Mr. McCutchan's comments. As for possible effects of hot-upsetting, we have examined many samples which compared structures produced by heating the steel to 1650 and 2200 F, respectively, and have observed no significant difference in graphitization. Therefore it seems unlikely that the structure from hot-upsetting is significant though, of course, there may be other effects of that operation which are.

The discussion of Mr. Rohrig is an important contribution and is greatly appreciated. Referring to the stress-relieving treatment just above the critical temperature, that was devised to eliminate the structure of the heat-affected zone and hence to remove what was thought to be the particular reason for the highly segregated type of graphite. The treatment at about 1400 F appears to be successful, though our experiments have shown that the random type of graphitization may actually be accelerated. Of course, it is only a corrective treatment and would not be needed with the right kind of steel. The other data which are contributed by Mr. Rohrig are all pertinent to the broad problem and are a welcome addition to the E.E.I.-A.E.I.C. program.

Studies on Susceptibility of Casting Steels to Graphitization

By J. J. Kanter,[1] Chicago, Ill.

This is a progress report for project No. 29 of the Joint A.S.T.M.-A.S.M.E. Committee on Effect of Temperature on the Properties of Metals. One of the activities undertaken by project No. 29 has been the study of certain aspects of the graphitization problem applying to the carbon-molybdenum casting steels used in welded piping structures. The steels so involved are of the types covered in A.S.T.M. Specifications A217 covering Pressure Alloy Castings Suitable for Fusion Welding such as valves, flanges, fittings, and other pressure-containing parts for high-temperature services. This investigation was undertaken in co-operation with the Manufacturers Standardization Society (M.S.S.) of the Valve and Fitting Industry, through a committee representing the constituent manufacturers engaged in the founding and manufacture of steel valves, flanges, and fittings.[2]

A program of tests was adopted by a group of manufacturers[2] from the valve and fitting industry for comparing the graphitization susceptibilities and general high-temperature stability of weldable grades of alloy cast steel using test castings in the form of a 4-keel block. This block, used by all of the investigators, is cast in green sand with the keels in the drag position, each fed from an end and through a risered mass above the keels as illustrated in Figs. 1 and 2. Fig. 1 shows the orientation of the casting as it is made, while Fig. 2 is a view of the four keels and the manner in which they are fed is more apparent.

The keels were removed from the blocks by sawing after heat-treatment, consisting of normalizing and drawing. The sawed surfaces of these keels were then machined flat. Upon the machined surface was deposited a single bead weld as illustrated in Fig. 3. The procedure in laying on the bead was essentially that established at Battelle Memorial Institute for the studies sponsored jointly by E.E.I.-A.E.I.C. The steel test coupon is placed in water at 60 to 65 F, at a level $^1/_4$-in. below the face machined for depositing, using end slugs for starting and finishing the bead. Using a $^5/_{32}$-in-diam type 7010 (C-Mo 0.50) electrode and a travel of approximately 6 ipm, the bead is deposited with direct-current negative polarity, at 25 to 30 volts and 125 to 135 amp.

After deposition of beads, the test specimens were given a stress-relieving heat-treatment at 1200 F. A cross section of a bead so deposited is illustrated in Fig. 4, showing the structure gradient between heat-affected zone and parent metal thus provided for study of susceptibility to segregated graphitization upon aging.

Drawing upon the experience at Battelle Memorial Institute in the E.E.I.-A.E.I.C. studies, aging treatments on the weld-bead cast-steel specimens have been made at 1025 F to attain an accelerated indication of graphitization susceptibility. Cur-

Contributed by the A.S.T.M.-A.S.M.E. Research Committee on Effect of Temperature on the Properties of Metals and presented at the Annual Meeting, New York, N. Y., November 26–29, 1945, of The American Society of Mechanical Engineers.

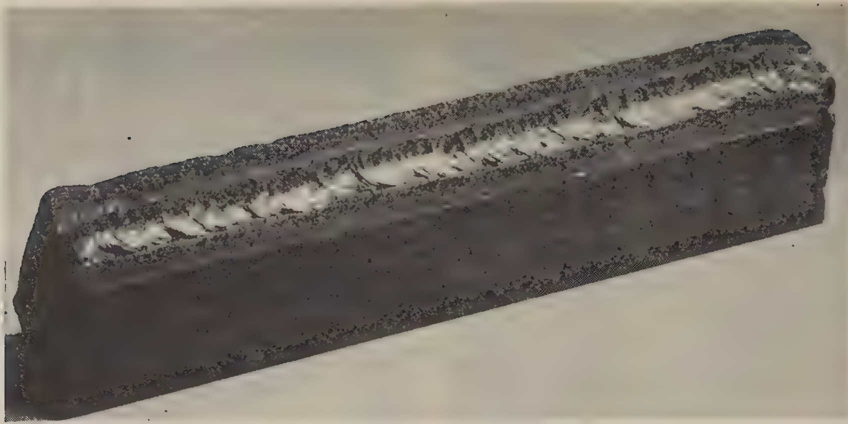

FIG. 3 WELD-BEAD SPECIMEN FOR GRAPHITIZATION TEST

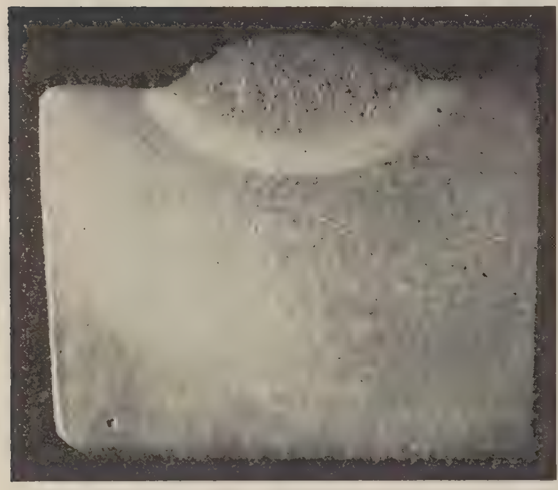

FIG. 4 ETCHED SECTION FROM SPECIMEN SHOWN IN FIG. 3 AT 3 DIAM

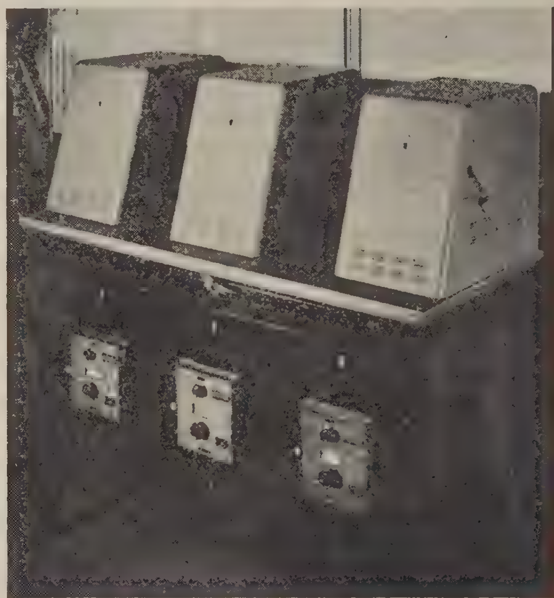

FIG. 5 ONE OF FOUR INSTALLATIONS OF FURNACES IN USE FOR AGING WELD-BEAD SPECIMENS SHOWN IN FIG. 3

rently, a number of studies in these series of tests are available for aging periods up to about 6000 hr and the specimens are continuing to age in furnaces at four of the co-operating laboratories. One of the furnace installations being so used exclusively for graphitization agings at 1025 F is shown in Fig. 5.

The original plan of the M.S.S. group was to survey the difference in graphitization susceptibility and stability of high-temperature properties in the carbon-molybdenum cast steels as made by various electric melting processes, namely, acid arc, basic arc, induction. Test heats by these processes were separately made using two types of deoxidation practice, including silicon addition, and silicon addition plus 2 lb aluminum per ton.

Almost unanimously, the co-operators reported difficulty and inability to obtain test-block castings free of "pinholes" using the straight silicon addition and it did not appear practicable from the standpoint of steel-pressure-vessel founding to consider such a practice. It was therefore decided to add another series of test materials using silicon addition plus $^1/_2$ lb aluminum per ton, which produced reasonably satisfactory test-block castings. Through this additional series of test castings it was expected that a variety of residual metallic aluminum contents would be obtained among the various heats, which would afford a basis for correlation with graphitization susceptibility.

Each co-operator furnished another set of test blocks by one or more of the electric melting processes containing 0.5 per cent of chromium in addition to the 0.5 per cent of molybdenum. These chromium-bearing castings were all made using the silicon plus 2 lb per ton aluminum-killing practice.

RESULTS OF STUDIES

The results of the studies from the cast-steel test bars upon observation after agings up to 6000 hr seem to bear out the already well-known contention that aluminum additions to carbon-molybdenum steels make for graphitization susceptibility as will be apparent from the comparison of photomicrographs, Fig. 6. A companion McQuaid-Ehn carburized structure is shown on this chart for each of the aged structures. It becomes further apparent that these tend to substantiate the Kerr-Eberle con-

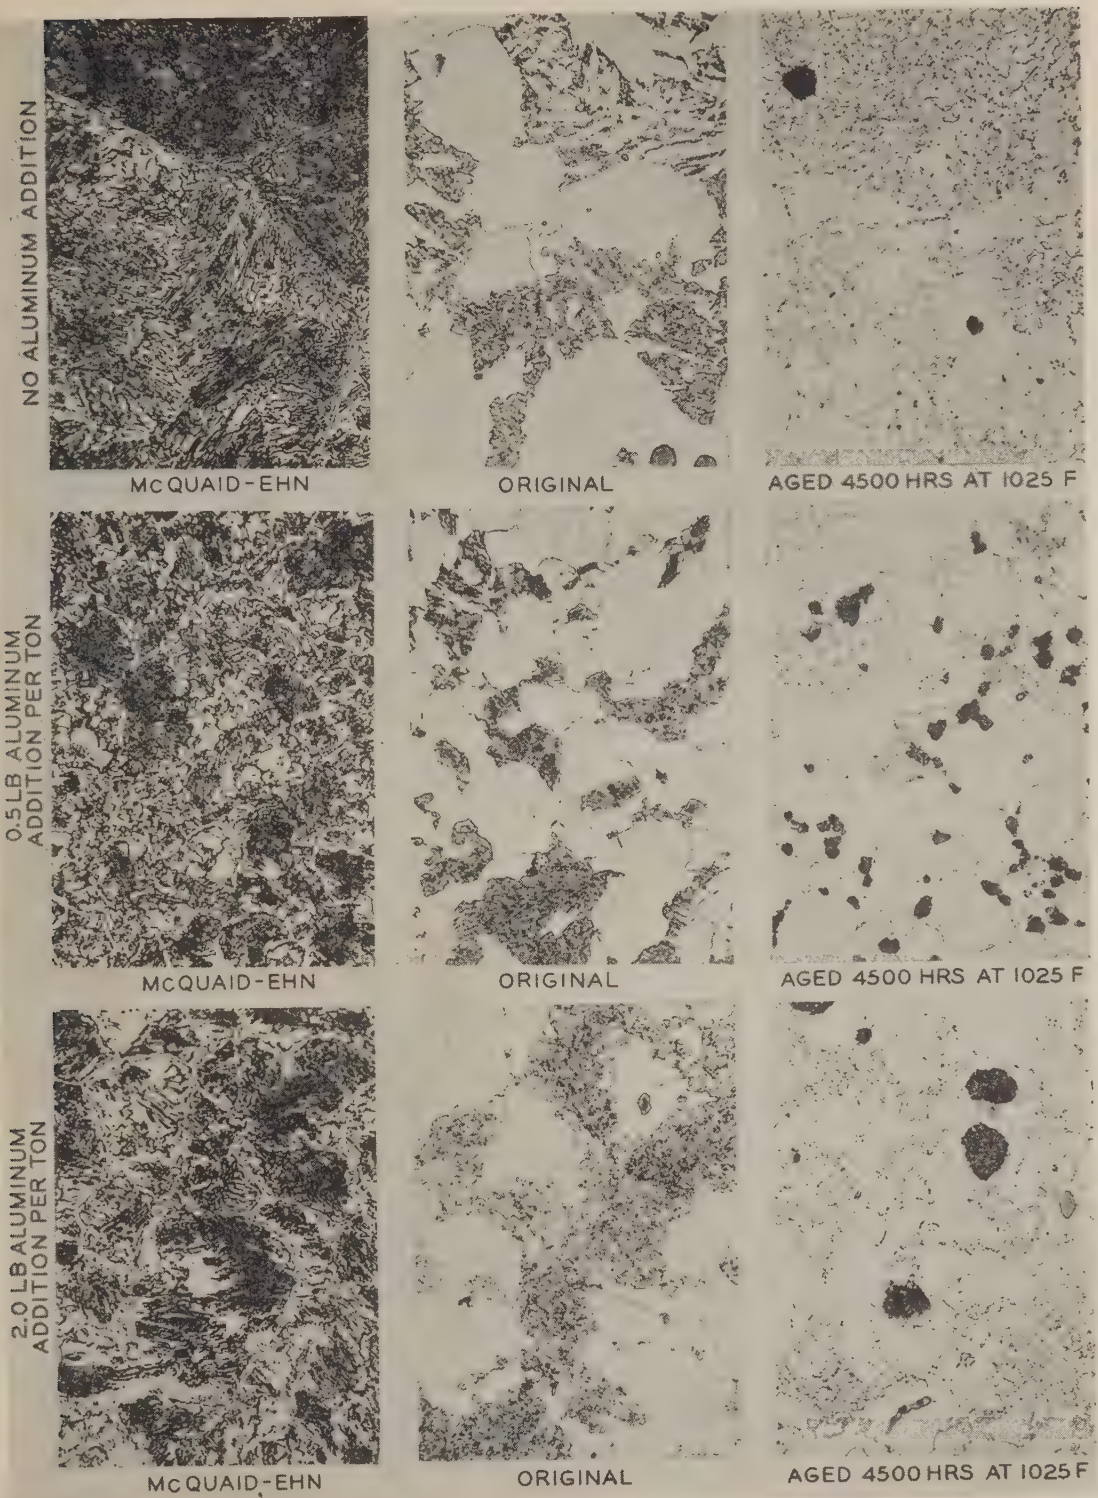

Fig. 6 Comparisons of Typical McQuaid-Ehn Carburized Structures for Carbon-Molybdenum Cast Steels With Structures at Heat-Affected Zone at 500 Diam

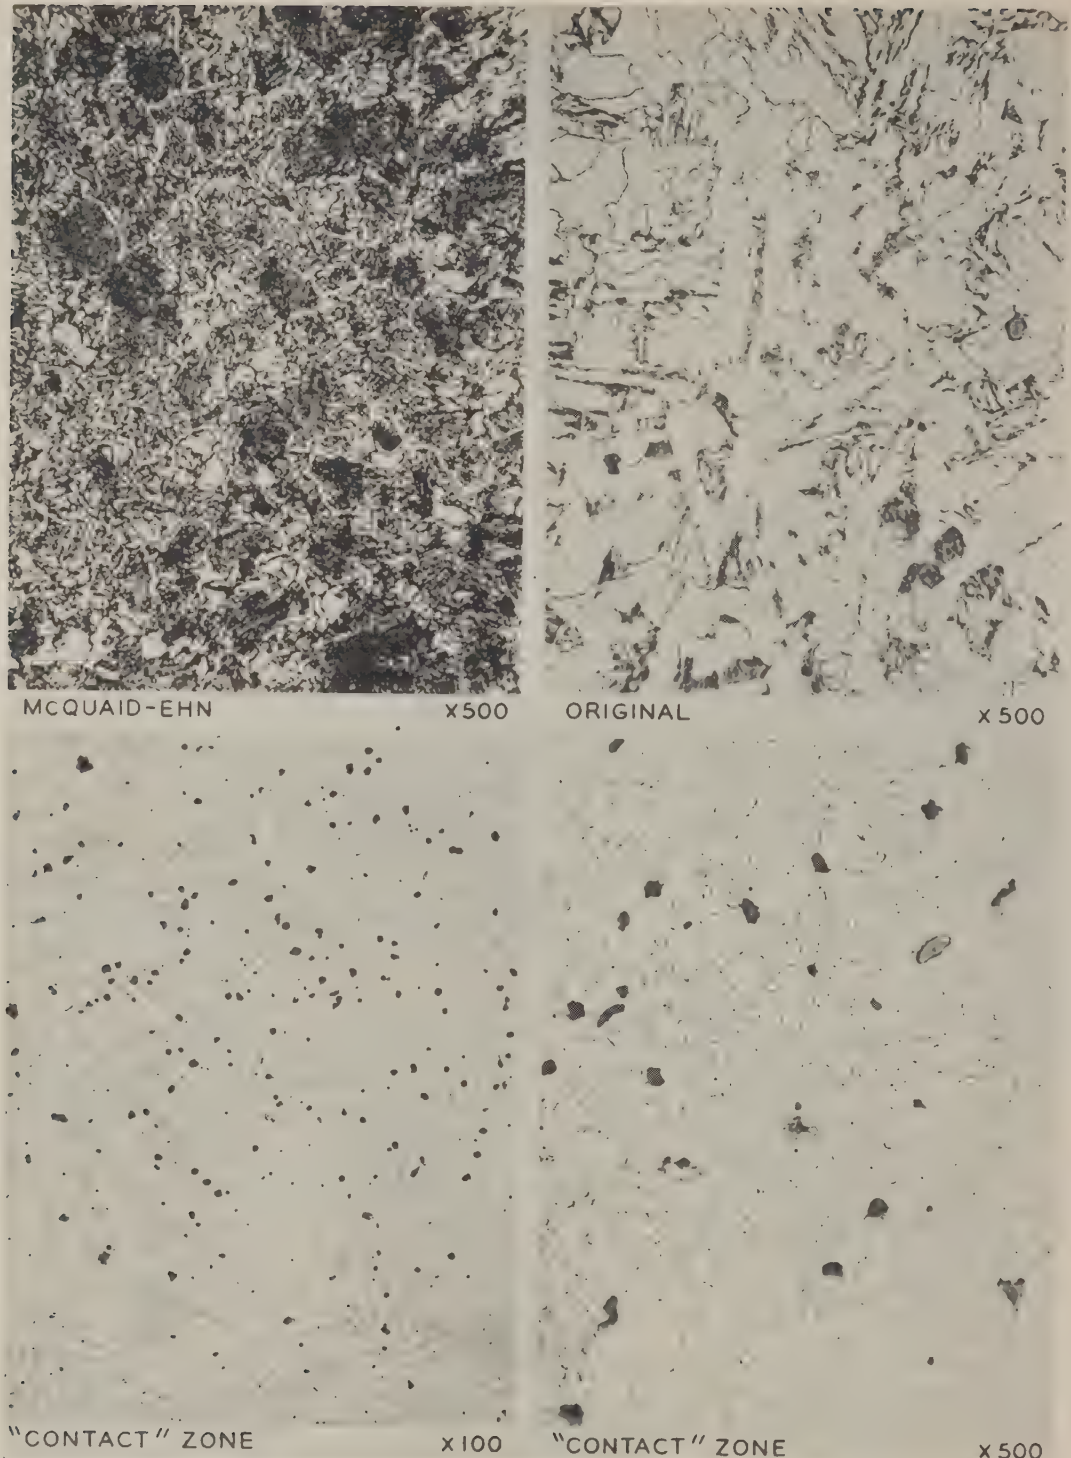

Fig. 7 Graphite Developed at Heat-Affected Zone of Carbon-Molybdenum Cast Steel With 2 Lb of Aluminum Addition per Ton, Normalized After Welding, Aged 4500 Hr at 1025 F

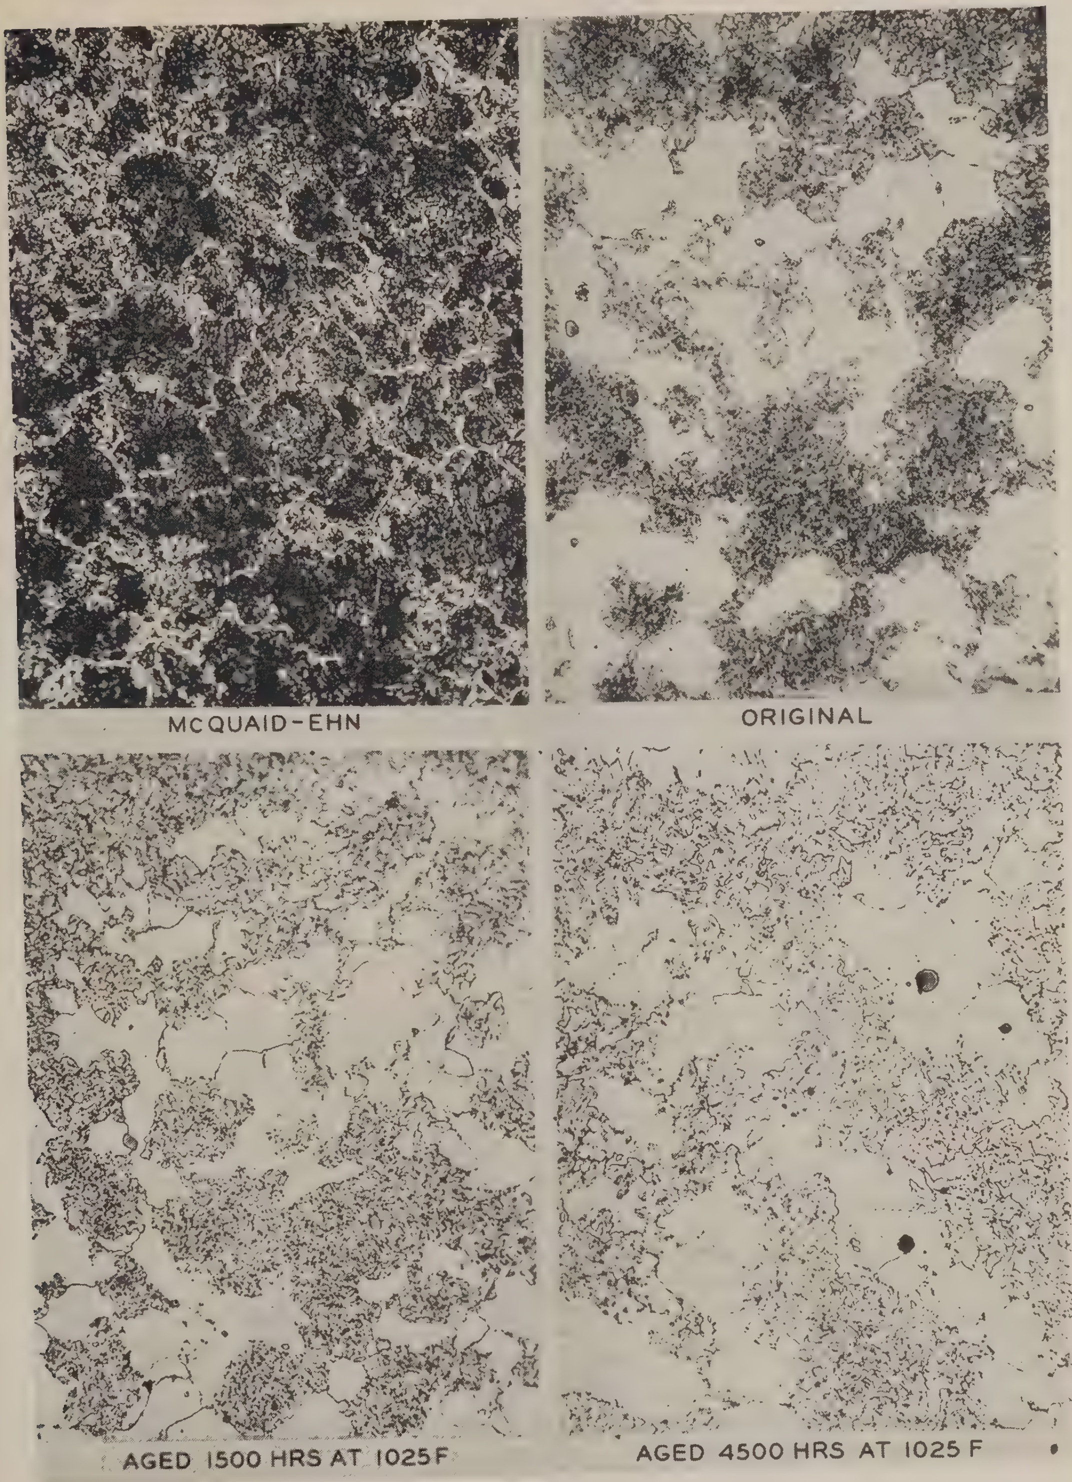

FIG. 8 TYPICAL STRUCTURES AT 500 DIAM OF CHROMIUM-BEARING CARBON-MOLYBDENUM CAST STEEL WITH 2 LB OF ALUMINUM ADDITION PER TON, AT HEAT-AFFECTED ZONE BEFORE AND AFTER AGING AT 1025 F

tention that "abnormal" structure by this criterion is an index of graphitization susceptibility in aluminum-treated carbon-molybdenum steels. This rule, however, does not necessarily apply to the steels having chromium additions. Study of microstructures indicates that the particular kind of electric-furnace process, all other factors being equal, is a minor influence as regards graphitization susceptibility.

One generalization which seems to apply with regard to the tests under discussion as well as much other observation, is that the inception of spheroidization agglomeration or coalescence of the carbide precedes its breakdown to graphite. A number of examples have been observed where in a single microfield, one spheroidized-carbide area will show graphite nodules, whereas an adjacent lamellar-carbide area will show no signs of graphite. Where chromium or other alloying ingredients prove effective in preventing graphitization under a certain condition of thermal history, the inhibition seems to be associated with resistance to spheroidization of the carbide. The susceptibility of aluminum-treated steel to graphitization seems to be associated with an accelerated tendency toward spheroidization.

In previous reports by the Joint A.S.T.M.-A.S.M.E. Committee, it has been apparent that strong aluminum treatment of steels led to easy spheroidization and consequent lack of creep resistance.

Proposals have been made to the effect that graphitization at the margin of the heat-affected zone or "contact zone" might be forestalled, or at least reduced to an impotent nature by a grain-refining normalizing heat-treatment subsequent to the welding operation. That such a treatment may not be effective in the case of a susceptible cast steel is evidenced by the micrographs, Fig. 7, comparing one of the weld-bead specimens normalized after deposition. It is seen that "contact zone" graphite has not been inhibited in this specimen. The transformation resulting from welding in the heat-affected zone seems to have some persistent effect, although it does appear that the zone of segregated graphite is somewhat broader, diffuses, and perhaps requires longer aging to detect. Studies upon more specimens normalized after welding are needed to clarify the effect.

Chromium in Cast Steels

In so far as the cast-steel studies have progressed (3000 to 5000 hr of aging), no definite evidence of graphitization has become apparent in any of the samples containing chromium in the range of 0.43 to 0.70 per cent as witnessed by Fig. 8, where relatively spheroidization-resistant carbides are well defined. It should be noted that the lowest chromium content is 0.43 and that the time periods involved are as yet relatively short and inconclusive.

It may eventually be determined that resistance to spheroidization is a necessary and perhaps sufficient condition to prevent graphitization over an expected service period.

Specimens of a number of the cast steels upon which the graphitization studies are being made are aging for the eventual purpose of making creep-strength studies on structures representing various stages of carbide deterioration. It has become quite apparent that graphitization has occurred in some of the coupons being aged for creep tests after advanced spheroidization of the carbide had developed. In the case of carbon-molybdenum steel with 2 lb per ton of aluminum addition, well-developed graphite is apparent after about 4000 hr of aging at 1025 F. The coupons containing 0.50 per cent chromium have shown no definite evidence of graphite after 5000 hr of aging. The committee has decided to continue the aging of all coupons for creep tests up to at least 10,000 hr before considering the starting of creep-rate determinations upon any of them.

Discussion

I. A. Rohrig.[3] This report shows that under suitable conditions graphitization may readily occur in cast as well as in wrought carbon-molybdenum steels. The observation of an apparent "persistent effect" resulting in segregated graphite in the heat-affected area of a weld even after normalizing is of particular significance because normalizing has appeared to be the most effective postwelding treatment for preventing segregated graphite. With respect to the normalizing of welds, the results of laboratory graphitization tests conducted on normalized welded samples by The Detroit Edison Company may be of interest.

A sample of high-aluminum carbon-molybdenum pipe mate-

Fig. 9 Segregated Graphite in the Heat-Affected Area of "As-Welded" Carbon-Molybdenum Sample After 10,300 Hr of Laboratory Test Heating

Fig. 10 Random Graphite in Former Heat-Affected Area of a Normalized Weld in Carbon-Molybdenum Sample That Was Laboratory-Heated for 10,300 Hr After Normalizing

rial was welded to low-aluminum material and then normalized by heating for 1 hr at 1725 F, followed by air-cooling. To promote graphitization, "as-welded" as well as "normalized" samples were heated at temperatures varied between 1000 and 1060 F for 3300 hr, and then at temperatures varied between 900 and 1150 F for an additional 7000 hr. After a total time of 10,300 hr of test heating, the as-welded samples showed a distinct segregation of nodular graphite in the heat-affected area whereas the normalized samples showed only random graphitization. Segregated graphite in the heat-affected area of as-welded high-aluminum material is shown in Fig. 9 of this discussion. Random graphitization at the former heat-affected area of the sample that was normalized after welding is shown in Fig. 10. Similar results were found in the low-aluminum material with the exception that considerably less graphite was present.

These results indicated that the normalizing treatment of 1 hr at 1725 F had been fully effective in removing the nucleation effect resulting from the heat of welding. Kerr and Eberle[4] have also reported on the apparent beneficial effect of normalizing after welding as a means of preventing the formation of segregated graphite. The results obtained from test prompt the suggestion therefore that the normalizing treatment used by the author, and which is not stated in the paper, may not have been fully effective in reconstituting and homogenizing the structure of the heat-affected area in his sample.

The author's suggestion that resistance to spheroidization may be a necessary and perhaps sufficient condition to prevent graphitization is probably based upon the hypothesis that spheroidization is the first stage of graphitization. Referring again to the work of Kerr and Eberle,[4] it is noted that they have reported on a number of cases in which steels that had spheroidized were found to be resistant to graphitization. Although spheroidization and graphitization may be parallel phenomena in steel at high temperature, it does not necessarily follow that spheroidization is the first stage of graphitization. In this association it might be pointed out that although the photomicrographs presented in Fig. 6 of the paper, are for the apparent purpose of showing the graphitization susceptibility of the aluminum-treated sample in contrast with the graphitization resistance of the sample having no aluminum addition, the two samples appear to be about equally spheroidized.

[4] Graphitization of Low-Carbon and Low Carbon-Molybdenum Steels" by H. J. Kerr and F. Eberle, A.S.M.E. pamphlet "Graphitization of Steel Piping," included in Trans. A.S.M.E., vol. 67, 1945.

Author's Closure

Mr. Rohrig's evidence that a sample of high-aluminum carbon-molybdenum pipe material, welded and normalized at 1725 F showed only random graphitization, is in interesting contrast to that on the carbon-molybdenum cast steels studied in the Project No. 29 investigation. Of seven different heats of carbon-molybdenum steel with 2 lb of aluminum addition per ton and normalized at 1650 F for one hour after welding by the various contributors of the specimens, all specimens showed a development of graphite after 5,000 hours of aging at 1025 F, of which the "contact" zone photomicrographs of Fig. 7 are typical. Since the presentation of the report in question, these aging tests have progressed far enough to show that upon 10,000 hours, the average degree of contact zone graphitization for the seven heats of steel normalized after welding is about the average degree which was obtained for a group of six similar heats of steel stress-relieved only after welding upon 4000 hours of aging. This degree of deterioration represents about one third of the carbon transformed to graphite. While normalizing has served to retard the development of graphite at the contact zone, it by no means promises to be a satisfactory measure of control for the carbon-molybdenum cast steels.

Mr. Rohrig questions the observation that spheroidization of carbide is a prelude to graphitization and supports his objection by pointing out that certain samples reported upon showed spheroidization but no graphitization. However, since the report was presented, examinations after 10,000 hours of aging at 1025 F have revealed further spheroidization and graphitization in a number of samples where it had not been found after 5000 hours, including those containing one half of one per cent of chromium, thus indicating that the development of graphite in sequence to spheroidization may be an eventual effect to be always considered relative to aging time, temperature stress, and the composition of the steel.

Comparative Graphitization of Some Low-Carbon Steels With and Without Molybdenum and Chromium

By G. V. Smith,[1] S. H. Brambir,[1] and W. G. Benz[1]

Study of several experimental heats of steel containing 0.5 per cent molybdenum and up to 1.20 per cent chromium showed that in steels containing 0.5 per cent or more of chromium, no graphitization occurred in 3000 hr at 1025 F; but this finding requires confirmation by study of additional heats, particularly of commercial manufacture. Additional studies relating to the effect of deoxidation practice, particularly in plain carbon steels, and of the effect of posttreatment of welds on graphitization are described.

Introduction and Summary

In continuation of investigations (1, 2, 3)[2] begun shortly after the now well-publicized pipe failure at the Springdale Generating Station of the West Penn Power Company (4), we have studied the occurrence of graphitization in the following samples:

1 Unwelded samples of 10 heats of 0.1–0.2 per cent carbon steel made and deoxidized differently.

2 A series of experimental heats of chromium-molybdenum steels to ascertain the effectiveness of chromium in preventing graphitization.

3 Molybdenum steel treated to simulate the structures occurring in the heat-affected region of a weld.

4 Molybdenum steel (0.5 per cent), which had been heated at 1300 F after welding, as a means of preventing localized graphitization in the heat-affected region.

The results are as follows:

1 In normalized samples from ten heats of 0.1–0.2 per cent carbon steel of different manufacturing and deoxidation practice exposed for 2000–3000 hr at 1025 F, graphite formed in only four steels. These four had been deoxidized with 2 lb or more of aluminum per ton of steel and were fine-grained and moderately abnormal in the carburizing test. Steels with 1 lb or less of aluminum per ton did not graphitize, even though in some cases slightly or moderately abnormal.

2 The results indicate that in a 0.5 per cent molybdenum steel at least 0.5 per cent chromium is necessary to prevent graphitization, but do not prove that this would always suffice. Experimental heats containing 0.5 per cent or more of chromium did not graphitize under the conditions of our experiments, no matter how they were deoxidized or treated before or after welding. This inference should be checked by additional tests on commercial heats, however, since, although a 0.25 per cent chromium—0.5 per cent molybdenum steel, deoxidized with more than 1 lb of aluminum, graphitized locally under certain conditions, a similar steel without chromium did not. Graphite did not form in the 0.25 per cent chromium—0.5 per cent molybdenum steel when the welded sample had been heated to 1300 F for 4 hr prior to exposure at 1025 F.

3 Simulation of the temperature-time cycles which occur during welding indicated that the maximum amount of graphite appears in that zone of the weld-heat-affected region which reached a temperature in the vicinity of 1400 F. This temperature is only an approximation and is interrelated with the time at temperature and cooling rate. Further confirmation was obtained of the efficacy of a 1300 F treatment, prior to simulated service, in preventing graphitization.

4 In a sample of pipe from the Schuylkill Generating Station normalized from 1650 F, graphitization was entirely suppressed by a treatment of 4 hr at 1300 F after welding and prior to simulated service. On the other hand, similar tests on samples which had not been normalized showed some graphite; exposure for 8 and 12 hr, instead of 4, at 1300 F still further reduced the amount of graphite to the point where it could hardly warrant concern.

I Graphitization of Ten Carbon Steels (0.1–0.2 Per Cent Carbon), Made and Deoxidized Differently, at 1025 F

Because of indications that manufacturing and deoxidation practices affect the tendency to formation of graphite in steels, we exposed samples of ten commercial carbon steels which happened to be available, in a furnace at 1025 F for a period of (*a*) 1000 hr, (*b*) 2000 hr, and (*c*) in the case of Nos. 1, 2, and 3, 3000 hr. The samples were examined metallographically for the presence of graphite, with results given in Table 1, along with the composition and mode of deoxidation of each steel. Each steel had initially been normalized from 1650 F; the samples were 3 in. long and $^3/_4$ to 1 in. thick. We also carburized[3] a sample of each steel and determined the resulting grain size and structure "normality" because of the recent claim that degree of "abnormality" is an indicator of tendency to graphitize.

Graphite was detected in only four of these ten steels, namely, in Nos. 7, 8, 9, and 10, as illustrated in Fig. 1. These four comprise all which had been deoxidized with 2 lb or more of aluminum, had residual aluminum in excess of 0.025 per cent, and were fine-grained; on the other hand, the six which did not graphitize had been deoxidized with not more than 1 lb of aluminum, had less than 0.007 per cent residual aluminum, and were coarse-grained. The four which graphitized were moderately abnormal, but so were some of those (Nos. 4 and 5) which did not; thus these limited data indicate that although carbon steels which graphitize are abnormal, the converse is not necessarily true. Consequently, the normality cannot be regarded as a reliable indicator of tendency to graphitize. More-

FIG. 1 TYPE AND AMOUNT OF GRAPHITE IN NORMALIZED CARBON STEELS
(*a*, No. 7; *b*, No. 8; *c*, No. 9; *d*, No. 10 of Table 1, after 1000 hr at 1025 F. Picral etch; ×500.)

over, according to these observations, the amount of residual aluminum, even though the accuracy of the analytical procedure is uncertain, appears to be a better indicator of tendency to graphitize than is the abnormality of the carburizing test.

The amount of graphite was greatest in steel 9, and progressively less in Nos. 8, 10, and 7, as determined by counting the number of nodules in the following manner: In an area at the center of the $^{3}/_{4}$-in. × 1-in. polished but unetched surface, the number of nodules in 50 fields 1 mm apart was determined after both 1000 and 2000 hr at 1025 F. To test whether a sufficient number of observations had been made to obtain a true picture, a second set of 50 observations was made, midway between the original ones. The results are given in Table 2.

TABLE 2 NUMBER OF GRAPHITE NODULES IN STEEL SAMPLES

Steel no.	Hours at 1025 F	Number of nodules in First 50 fields	Second 50 fields	Total 100 fields
7	1000	2	2	4
	2000	4	9	13
8	1000	77	88	165
	2000	123	114	237
	1000	191	202	393
	2000	272	257	529
10	1000	16	22	38
	2000	31	28	59

Taking into account both this number and the size of the nodules in Fig. 1, it is evident that the amount of graphite is greatest in steel 9 and progressively less in steels 8, 10, and 7. It was hoped that the counts would also provide an indication of whether the number of graphite nuclei is limited or increases with time. The data appear, on first thought, to show an increase; but when it is considered that nodules already present continue to grow, and that the chance of intersecting a nodule (by the plane of polish) increases with its size, it is realized that the evidence is insufficient to permit any decision on the matter.[4] It can be said, however, that if new nodules form, their rate of appearance between 1000 and 2000 hr at 1025 F is not great.

[4] If the nodules were uniform in size (which they probably are not), the number counted should increase in proportion to the increase in radius, and since this number did not even double (except for steel 7), it would be necessary to make precise measurements of nodule size and size distribution.

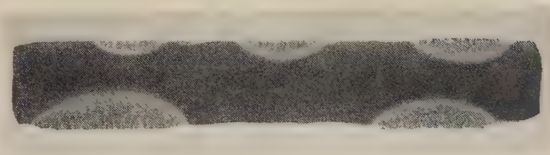

Fig. 2 Longitudinal Cross Section of Weld Sample Employed in Second Section of Paper

(Weld deposited for $^{1}/_{2}$, 1, 2, 4, or 8 sec. Nital-picral etch; ×1.)

The amount of graphite in the several steels could not be correlated with chemical composition nor with initial microstructure.

II Effectiveness of Chromium in Preventing Graphitization of 0.5 Per Cent Molybdenum Steel

Among the suggestions for preventing graphitization in 0.5 per cent molybdenum steel is that of adding chromium, which is one of a group of elements that, when present in sufficient proportion, combine with carbon in steel to form so-called alloy carbides. Molybdenum, also one of this group, is reputed (5) to possess stronger affinity for carbon and presumably forms a more stable carbide than does chromium; consequently, if carbide stability is a factor, there is no a priori reason for thinking that chromium addition will be more effective than equivalent increase in molybdenum.

Materials and Procedure. In an effort to ascertain whether chromium is effective in preventing graphitization and, if so, the minimum amount necessary, we investigated a number of heats with 0.5 per cent molybdenum and up to 1.20 per cent chromium, deoxidized with $^{1}/_{4}$ or $1^{1}/_{4}$ lb of aluminum per ton or with ferrosilicon-zirconium, as listed in Table 3. These were 20-lb induction-furnace heats, forged to $^{1}/_{2}$-in. × 1-in. bars, which were cut into 3-in. lengths. Two specimens of each were heated at 1450, 1650, or 2200 F for $^{1}/_{2}$ hr and air-cooled. After rough-grinding to remove scale, five weld deposits were made on each sample, as illustrated in Fig. 2, using molybdenum-steel weld rod ($^{3}/_{16}$-in. Murex C-Mo 50); the rod was held for $^{1}/_{2}$, 1, 2, 4, or 8 sec at different locations, the sample being cooled to room temperature before each deposit. In this manner, it was hoped that the effect of steepness of the temperature gradient through the heat-affected region during welding could be determined, since an earlier study (3) showed susceptibility to graphitization to be greater the steeper this gradient. One of each pair of specimens was then heated 4 hr at 1300 F to determine the effectiveness of this posttreatment in preventing localized graphitization (1, 3). All samples were then heated for 3000 hr at 1025 F in a muffle furnace, after which they were sectioned longitudinally through the weld deposits, and examined microscopically for graphite.

We also carburized a sample of each steel,

Note: Sulphur and phosphorus were less than 0.035 or 0.01 per cent, respectively, in steels I, J, K, and L and were not determined in the remainder.

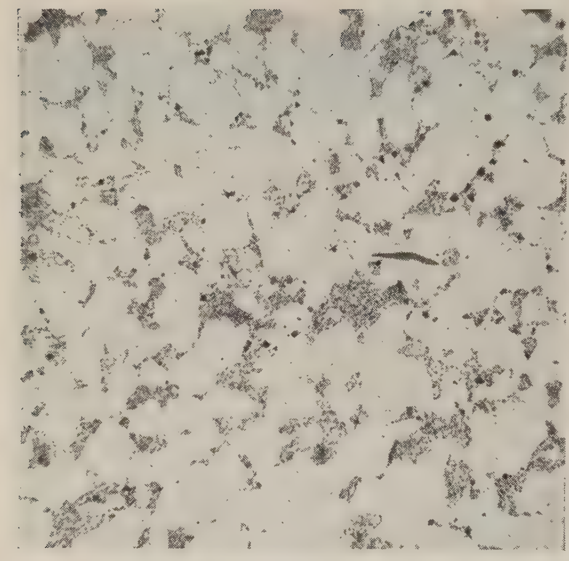

Fig. 3 Graphite in Heat-Affected Zone of Weld in Steel D, $^1/_2$ Mo-$^1/_4$ Cr, After 3000 Hr at 1025 F
(Picral etch: ×500.)

and determined the resulting grain size and normality, with results given in Table 3.

Results and Discussion. Only two samples definitely graphitized; these were both of steel D, 0.25 per cent chromium-0.5 molybdenum, deoxidized with $1^1/_4$ lb of aluminum per ton. In the samples of this steel normalized from 1450 or from 1650 F before welding, graphite formed in the heat-affected region of all welds, the amount being not appreciably different among the welds, contrary to our earlier finding (3). The graphite nodules were quite small, Fig. 3, and only a very few were found in unaffected base metal. No graphite was observed in the companion samples heated 4 hr at 1300 F after welding and prior to exposure at 1025 F, in further confirmation of the efficacy of this proposed preventive treatment (1, 3), nor was any found in samples previously normalized from 2200 F, confirming a tendency, reported earlier (3), toward increased resistance to graphitization of structures resulting from normalizing at high temperature.

None of the others showed any graphite in any condition of prior or posttreatment, with the possible exception of B, normalized at 1650 F before welding and not heated at 1300 F after welding. In this there were several widely scattered nodules which appeared to be graphite, but because they were so small and so few, we cannot be certain. That this steel did not graphitize more extensively, in one or more original conditions, was unexpected, since it was thought that the molybdenum steel would be more prone than the chromium-molybdenum to form graphite.

This possible inconsistency in behavior emphasizes again the danger of basing claims on observations on a small number of heats; the results do indicate, however, that more than 0.25 per cent chromium must be present in order to inhibit localized graphitization.

All these steels were to some extent "abnormal" in the carburizing test except I, the plain 0.5 per cent molybdenum steel deoxidized with ferro-silicon-zirconium. Because of lack of graphitized steels in this series it is not possible to correlate "abnormality" with tendency to graphitization. However, the normality ratings are of some interest in themselves, showing, for example, that it is difficult to produce a strictly normal steel; that 0.5 per cent molybdenum steel is "normal" when deoxidized with ferro-silicon-zirconium confirms an earlier finding (7).

III Simulation of Structures of Heat-Affected Region Which Graphitize

It has been shown that the zone of localized graphitization in welded molybdenum steels is that which during welding reached a temperature slightly above the lower critical, A_1 (1340 F). To learn more about this phenomenon, samples of a molybdenum steel, susceptible to graphitization, were heated for short times in the range 1350–1450 F, and gradiently cooled, thin samples being used to insure rapid temperature change.

From a sample of Springdale Station[5] pipe, air-cooled as a $^3/_4$-in. section after $^1/_2$ hr at 1650 F, a number of samples approximately $^1/_{16} \times {}^1/_4 \times 1$ in. were prepared. Using a coke-covered, deoxidized lead bath held at constant temperature within the range 1350–1450 F, and tongs heated to the bath temperature, one end of a sample was grasped in the tongs, and the whole immersed in the lead bath for $^1/_2$ min; its free end was then immersed to a depth of $^1/_4$ in., in water at room temperature and held until reasonably cool. A duplicate set of samples was treated at each of the temperatures 1350, 1375, 1400, 1425, and 1450 F. Each set was then sealed, in vacuo, in a silica bomb to prevent subsequent oxidation and decarburization, and one of these was heated at 1300 F for $4^1/_2$ hr; both were held for 1000 hr at 1025 F, and each sample was then examined metallographically upon a longitudinal section for graphite.

The samples were held for only $^1/_2$ min in the lead bath, because we thought this might simulate welding conditions. In such a short time at only slightly above the lower critical temperature, there is time for only partial transformation of ferrite and carbide to austenite, and the small regions, necessarily rich in carbon, of this latter constituent presumably set the stage for localized graphitization (1). The specimens were gradiently quenched to provide a progression of cooling velocities, one of which should correspond to the fairly fast rate of the heat-affected region of a weld.

After 1000 hr at 1025 F, graphite was observed in each of the five samples which had not received the 1300 F treatment, but not in any of the companion five which had been so treated. The photomicrographs in Fig. 4, taken approximately $^1/_4$ in. from the quenched end, show a comparison of the five samples. The 1350 F sample showed no graphite in the quenched zone, Fig. 4(*a*), but there were a few small nodules in the tong-held end. At 1375 F there was some graphite near the quenched end, Fig. 4(*b*), but practically none in the opposite end. The quenched zone of the 1400 F specimen, Fig. 4(*c*), showed the maximum amount of any sample, and the tong-held end showed an intermediate amount. At 1425 F the amount in the quenched zone had decreased sharply, Fig. 4(*d*), and there was an appreciable amount in the tong-held end. At 1450 F there were very few nodules at either end, Fig. 4(*e*).

Thus these experiments indicate that graphite forms most readily in that portion of the heat-affected region which, during welding, was at a temperature in the neighborhood of 1400 F. This is only an approximation since our holding time of $^1/_2$ min may not exactly simulate welding conditions; the temperature in any event is not critical. The experiments also indicate that cooling rate is significant. That no graphite occurred in any sample postheated at 1300 F provides further confirmation (3) of the utility of this treatment.[6]

IV Posttreatment at 1300 F as a Preventive of Localized Graphitization

Sometime ago we suggested (1) that localized graphitization

[5] Of West Penn Power Company, where the problem first arose (4).

FIG. 4 REPRESENTATIVE REGION NEAR QUENCHED END OF THIN SAMPLES OF 1/2 PER CENT MOLYBDENUM STEEL
(Heated to *a*, 1350 F; *b*, 1375 F; *c*, 1400 F; *d*, 1425 F; and *e*, 1450 F, for 1/2 min and gradiently quenched, then heated at 1025 F for 1000 hr. Picral etch; ×1000.)

might be avoided by heating to 1300 F after welding and prior to service, and recently obtained experimental corroboration (3) of the efficacy of this treatment on samples of Springdale Station pipe.[5]

Shortly after our results were published, H. Weisberg of Public Service Electric and Gas Company, reported privately that he had been unable to prevent graphite formation by using this suggested treatment although its amount had been reduced; he then kindly supplied us with a sample of his steel, which was used in the following experiments.

The samples were reported to be from a 0.5 per cent molybdenum-steel pipe manufactured by National Tube Company, Heat No. 6532, in 1937 to A.S.T.M. specification A158-36, Grade P-1, was deoxidized with 1.8 lb of aluminum per ton, and was furnished for the Philadelphia Electric Company's Schuylkill Station as annealed between 1350 and 1400 F. It had not been

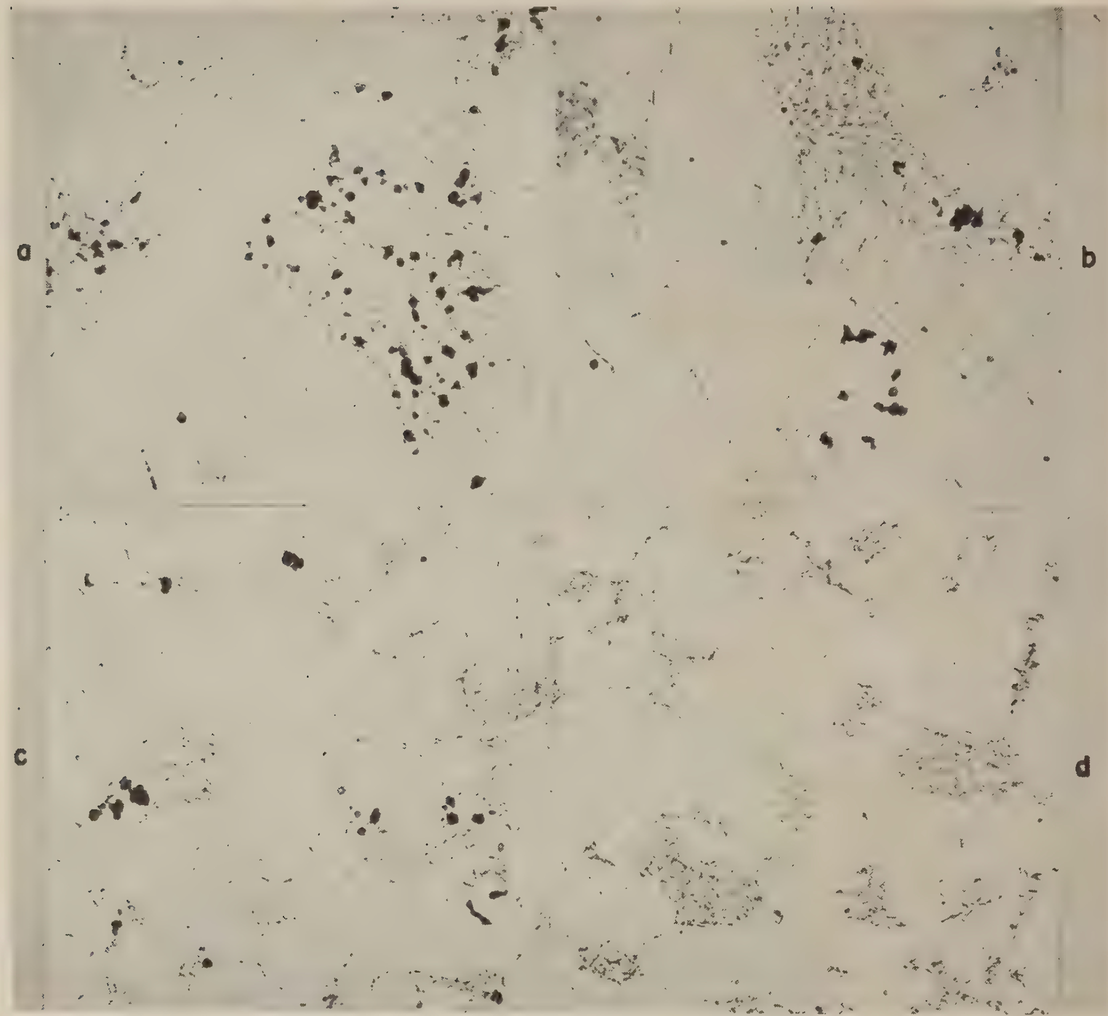

FIG. 5 GRAPHITIZATION IN HEAT-AFFECTED REGION OF 1/2 PER CENT MOLYBDENUM STEEL FROM SCHUYLKILL STATION PIPE AFTER 1000 HR AT 1025 F

(Picral etch: ×500.)

(*a*, As-received, not posttreated; *b*, as received, posttreated 4 hr at 1300 F; *c*, normalized 1650 F, not posttreated; *d*, normalized 1650 F, posttreated 4 hr at 1300 F.)

in service but had, in the course of Mr. Weisberg's experiments, been subjected twice to a 1200 F "stress-relief" treatment.

Since in our earlier experiments (3) with the Springdale Station pipe, we had normalized the samples prior to test, and since Mr. Weisberg had conducted his tests in the as-received condition, we decided to test in both conditions. Accordingly, two specimens approximately $1 \times 2^1/_4 \times 3^3/_8$ in. were prepared, one as received, the other normalized $^1/_2$ hr at 1650 F. Upon each of these a "narrow" and a "wide" weld bead, illustrated in Fig. 6, were laid down according to the following conditions:

Preheat	None	
Electrode	Murex C-Mo 50	
Weld type	Bead weld deposited in flat position	
	Narrow	Wide
Current, amp	200	285
Arc voltage, volts	28	30
Speed, ipm	9	3
Heat input, Btu per in	37	171

The purpose in having both a narrow and a wide weld bead was to obtain further information on the effect of steepness of temperature gradient in the heat-affected region. After welding, each sample was cut in half and one half heated 4 hr at 1300 F and air-cooled; all four were then heated 1000 hr at 1025 F, sectioned, and examined microscopically.

Figs. 5(*a*), (*b*), (*c*), and (*d*), representing the structure of the low-temperature zone of the heat-affected region of the narrow weld bead of each sample, illustrate the results. In the as-received sample, not heated at 1300 F after welding, much graphite had formed, Fig. 5(*a*), but the companion section heated at 1300 F after welding showed considerably less, though there was some, Fig. 5(*b*), corroborating Mr. Weisberg's finding. The sample normalized before welding also showed considerably less graphite, Fig. 5(*c*), and the companion section heated at 1300 F after welding showed none at all, confirming our earlier observations on the normalized Springdale Station pipe. In those which had graphitized the amount was greater in the heat-affected region of the narrow than of the wide weld bead. Graphite was not observed in the unaffected base metal of any sample.

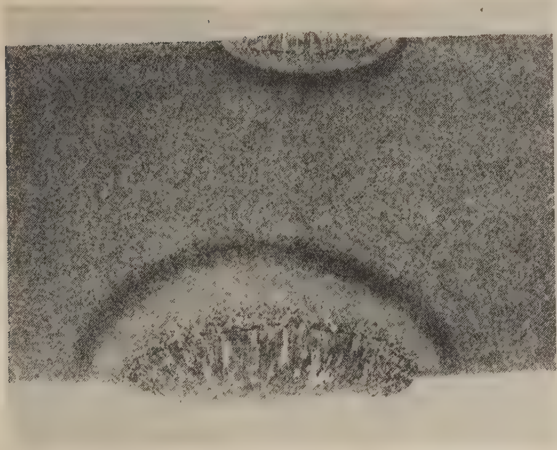

Fig. 6 Transverse Cross Section of Weld Sample Employed in Section IV
(Nital-picral etch: ×2.)

We do not know why graphite formed in the as-received but not in the normalized sample heated at 1300 F after welding. As apparent in Fig. 5, the as-received material was coarse-grained, indicative of a comparatively high temperature during its last supracritical treatment; this, however, probably would contribute to greater rather than to less resistance.[7] One suspicious factor is the 1350–1400 F annealed condition in which presumably the steel was furnished, this being the range (see preceding section) in which the stage is set for graphitization in the heat-affected region of a weld. With this beginning, the two stress-relief treatments at 1200 F which the material had undergone, may have so stabilized the graphite nuclei that they were not dissolved by subsequent heating for 4 hr at 1300 F,[8] i.e., treatment at 1200 F may have initiated the formation of graphite, but was too short to result in visible nodules. Some credence is given to this hypothesis by the results of the following experiment:

Upon another as-received sample a weld bead was laid under conditions identical with those just described for the narrow bead (since this produced more graphite). The sample was then cut in half, and one half heated for 8 hr, the other for 12 hr at 1300 F; both were then exposed for 3000 hr at 1025 F and examined microscopically. Both samples contained graphite in the heat-affected region, but in such small amount that it was difficult to find; Fig. 7 illustrates the largest amount. The amount appeared to be about the same in both samples,[9] and none was observed in the unaffected base metal of either. Thus longer heating at 1300 F resulted in considerably less graphite, presumably because the graphite nuclei had been dissolved or had reverted to carbide.

[7] See reference (3) and also the second section of this paper.

[8] In an earlier paper (2), we showed that graphite in a similar steel could be caused to revert to carbide by heating at 1300 F.

[9] On afterthought, it is realized that the choice of 12 hours was poor; 16 or 24 hours would have been better.

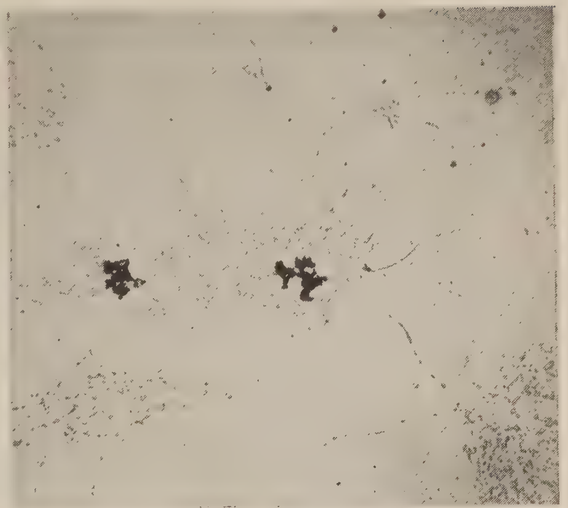

Fig. 7 Most Severe Graphitization in Heat-Affected Zone of Schuylkill Station Pipe Welded in "As-Received" Condition and Then Posttreated 8 Hr at 1300 F and Held at 1025 F for 3000 Hr
(Picral etch: ×500.)

Acknowledgments

Dr. R. F. Miller of Carnegie-Illinois Steel Corporation and Mr. E. C. Wright of National Tube Company furnished the steels studied except for item 4, which was supplied by Mr. H. Weisberg of the Public Service Electric and Gas Company, and for a sample of the Springdale pipe supplied by Mr. R. W. Emerson of Pittsburgh Piping and Equipment Company.

Further Observation of Graphitization in Aluminum-Killed Carbon-Molybdenum-Steel Steam Piping

By R. W. EMERSON[1] and MATHEW MORROW[2]

Among graphitization of steel pipe studies being carried on, the present one deals with what the authors have termed "slip-plane" graphitization, which describes a condition of graphite segregation along slip planes where local "yielding" or localized plastic deformation had previously occurred. Such graphitization has been found to vary widely from the outside to inside of a pipe and from quadrant to quadrant around the pipe periphery. It has been determined that "nodular" graphite segregation whether of the "isotherm" or slip-plane type is as effective as "chain" graphite in reducing the ductility of low-carbon or low-carbon-molybdenum steel.

Introduction

The graphitization of steel containing less than 1 per cent carbon and particularly less than 0.2 per cent carbon, at subcritical temperatures although reported in the literature (1)[3] was, prior to 1943, of little more than academic interest.

The complete circumferential failure of a carbon-molybdenum-steel steam pipe in January, 1943, which was attributed to subcritical graphitization, and the subsequent discovery of the same phenomenon in pipe lines in many other high-temperature steam power plants during the past 3 years has, however, resulted in the establishment of numerous intensive research programs which have been sponsored by both private industry and joint investigating committees. The results of these various investigations have been viewed by both the consumer and the producer with increasingly keen interest.

A report of the failure mentioned was given, together with three other papers dealing with graphitization, before this Society in December, 1943 (2, 3, 4, 5). The many investigations which have been carried out during the past 3 years have shown that graphite tends to segregate along the extremity of the heat-affected zones of welded joints, provided the steel is one in which the carbide is potentially unstable.

In February, 1945, however, routine sampling of several joints at the Springdale Power Station, at which station the original failure occurred, revealed a condition of graphite segregation which was not only of a serious nature, but one which was totally different from anything previously encountered. Whereas the terms "isotherm" and "eyebrows" were used to describe graphite segregation encountered adjacent to welded joints, due both to the location and macroscopic appearance of the graphite, the authors have chosen in this case the term "slip-plane" graphitization, to describe a condition of graphite segregation which appears to have unquestionably occurred along slip planes where local "yielding" or localized plastic deformation had previously occurred.

Although the discovery of slip-plane graphitization adds further to the general field of knowledge about graphitization, it also points to the over-all complexity of this general problem with which we are dealing.

Location of Slip-Plane Graphitization

In sharp contrast to "isothermal" graphitization adjacent to welded joints, slip-plane graphitization varies markedly from ID to OD and from quadrant to quadrant on the pipe periphery. For this reason the location of the graphitized area with respect to the boiler lead in which the difficulty was found, as well as its location with respect to the original failure, is given in Fig. 1. Twelve inches of pipe, including the upset pipe end of No. 4 boiler lead, was removed at the time of the failure in January, 1943. This was replaced by a spool of pipe from one of the three heats of pipe originally used in this installation in 1937. This pipe, however, had never been in service and was used without

(Graphitization runs from OD to ID and on 45-deg angle with respect to longitudinal direction of pipe. Plastic deformation along planes of maximum shear stress is believed to be responsible for nucleation of graphite.)

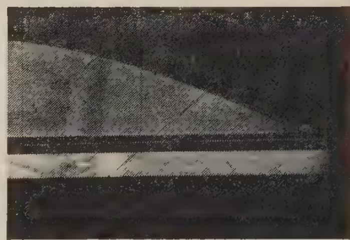

Fig. 2b Circumferential Cracks at OD Which Run at a 45-Deg Angle to Direction of Pipe Rolling

upsetting. Joints 4-1 and 4-1A as shown in Fig. 1, were welded, using a 400 F preheat and a 1200 F stress-relieving heat-treatment.

In January, 1944 (1 year later), $1^1/_2$-in-diam trepanned plugs were removed from both the inlet and outlet sides of joints 4-1A and the inlet (pipe) side of joint 4-2. Microscopic examination revealed incipient graphitization of the 12-in. spool as well as a mild reinfection (graphitization) of both the outlet side of joint 4-1A and the inlet side of joint 4-2. Segregated graphite of a serious nature, however, was not present in the plugs examined.

In February, 1945 (2 years later), "weld-prober" specimens were removed from the same two joints at approximately 45 deg from the location of the trepanned plugs.

During the preparation of the specimen from joint 4-1A it was observed that two cracks were present in the old pipe which had all the characteristics of previously encountered graphite segregation but which were in no way associated with the extremity of the heat-affected zone. Further examination revealed that these cracks, although extending from the OD toward the ID to a depth of $^5/_8$ in., did not run transverse to the direction of rolling on the pipe circumference but rather at an angle of 45 deg to the direction of rolling. The pattern of the cracks, as shown in Fig. 2, is typical of that which is produced in material which fails by shear.

Inasmuch as this condition existed across the entire width of the weld-prober specimen and not knowing to what extent it continued into the pipe or whether or not additional planes of graphite were present in the pipe remaining in service, it was deemed advisable to replace the entire bend between the superheater header and nonreturn valve as shown in Fig. 1. This pipe bend was accordingly removed on March 2, 1945, and replaced by a 1 per cent chromium 0.5 per cent molybdenum steel having an analysis comparable to A.S.T.M. Specification A 213 Grade T-12.

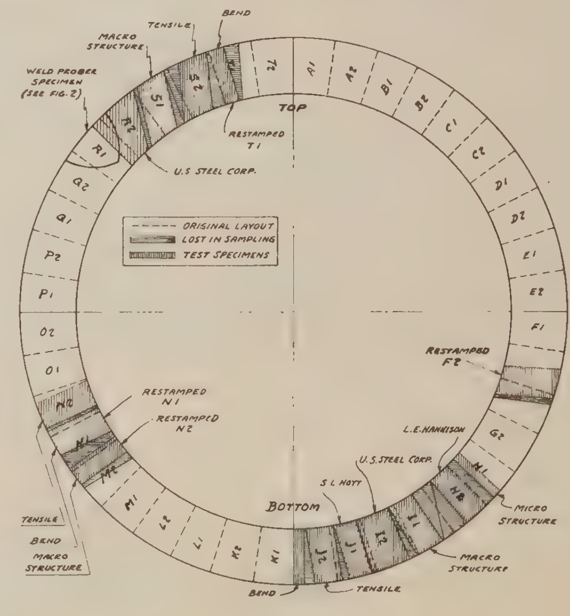

Fig. 3

Results of Macroscopic Investigation

In an effort to determine the extent of the grossly segregated slip-plane graphitization which was found in the weld-prober specimen from joint 4-1A, a 13-in. section from the bend was removed, comprising the joint mentioned, 4.75 in. of the 12-in-long spool which was installed at the time of failure, and 7.25 in. of the old pipe which had been in service since 1937, and which extended to a distance of 19 in. from the original failure.

Having previously found that heavily segregated graphite could be made visible to the unaided eye by either rough-grinding or machining, the surface of the 13-in. length of pipe was "turned" in a lathe to obtain a clean machined surface on both the OD and ID (2, 12).

After machining, the pipe section was stenciled in accordance with Fig. 3, and subsequently quarter-sectioned longitudinally. Before removing any test pieces, however, both the inside and outside pipe surface of each quarter-section was photographed. Figs. 4 to 7, inclusive, show the severity of slip-plane graphitization as revealed by surface-machining only. It is to be emphasized that no special machining, grinding, polishing, or etching techniques are required to locate heavily segregated graphite such as shown in Figs. 4 to 7, inclusive.

Several distinct lines of heavily segregated graphite, running at both a plus and minus 45-deg angle, can be seen in the upper right-hand corner in Fig. 4. (Section F-1 to J-2, inclusive, see Fig. 3.) A multitudinous number of fine lines of segregated graphite are also present in the upper center of Fig. 4. A good example of "isotherm" graphitization (graphite segregation at the extremity of a weld-heat-affected zone) is shown by the semicircular pattern in the upper left of this figure. This condition was produced by the fillet-welding of a 1-in-sq bar to the pipe, apparently for mechanical reasons during the original erection of this piping. This in effect is the result of a "weld-bead" test similar to that devised and used by Battelle Memorial Institute, and others in 1943, as a simple test for determining the susceptibility of steel to graphitization. The bead test shown in this illustration, however, was given an aging treatment of 935 to 950 F for approximately 65,000 hr (actual operating conditions), as contrasted with the artificial accelerated aging tests of 2000 to 8000 hr or longer at 1000 to 1050 F. Also present in Fig. 4 are several lines of graphite adjacent and running into weld joint 4-1A.

Lines of heavily segregated graphite running at both plus and minus 45-deg angles as well as a multitudinous number of the finer lines of graphite were found in section K1 to 02 inclusive (see Fig. 3). This is shown in Fig. 5. In addition to the foregoing, many other small speckled patches of localized graphite segregation of unknown origin are present in this figure. It is to be pointed out that lines of heavily segregated graphite are not present in the location of the trepanned plug (upper left, Fig. 5) which was removed in January, 1944. This plug was removed from the side of the pipe at the location 02-P1 shown in Fig. 3. Metallographic evidence, however, indicated that not only was heavily segregated slip-plane graphitization present at the time this plug was removed in 1944, but that this condition actually existed at the time the 12-in. spool was welded into the line in January, 1943. When sampling pipe for evidences of slip-plane graphitization therefore it cannot be overemphasized that the mere fact that such a condition is not detected in a test specimen does not mean that such a condition is nonexistent in the general vicinity of such a test specimen.

The location of the weld-prober specimen, the macrographs of which are shown in Fig. 2, is shown in Fig. 6 (section P1 to T2, inclusive), and it may be seen that it was coincidental that the location was so chosen that the heavily segregated slip-plane graphitization was intersected by the specimen removed. Had the specimen been removed anywhere between section A1 and E2 this condition would have gone undetected, and this pipe might possibly still be in service. The longest length of slip-plane graphitization, shown in Fig. 6, was found to be 4.5 in.

The inside pipe surface was machined to determine if the condition described could be located on the inside pipe surface or if the graphite segregation found on the outside of the pipe had actually penetrated the entire pipe wall. The condition found on the inside pipe surface, although confined to sections F1 to M2, is believed to be even a more striking example of a graphitization pattern, the orientation of which is unquestionably the direct result of stress.

Having observed the macroscopic appearance of both the inside and outside pipe surface, Figs. 8, 9, and 10 illustrate the graphite pattern found through the pipe wall at sections I1 and S1. A roughly ground and unetched view of section I1 is shown in Fig. 8 at normal magnification.

The same section as shown in Fig. 8 is shown in Fig. 9, after polishing and deep-etching in hot 50 per cent hydrochloric acid. This illustration which takes in a larger area than Fig. 8, is shown at two magnifications.

Since many of the lines of graphite segregation appear to emanate from the weld, it first appears that these lines formed as a result of and after joint 4-1A was completed (January, 1943). On the contrary, however, close examination of this figure reveals that these lines have been partially eradicated along the heat-affected zone of the weld. Microscopic observations further substantiate that re-solution of the graphite took place in the heat-affected zone as a result of the localized high temperature during the rewelding of this joint. This fact was subsequently substantiated by G. V. Smith and S. H. Brambir, U. S. Steel Corporation Research Laboratory (14). Furthermore, had the lines of graphite shown in Fig. 9 been initiated at the time of or subsequent to the welding of joint 4-1A, the condition of stress which initiated the graphite pattern in the old pipe would have been transmitted through the weld into the 12-in. spool and it would therefore be expected that similar lines of graphite segregation would be present in the 12-in. spool which was installed at the time joint 4-1A was made, and which was of similar chemistry and deoxidation as the original pipe.

Still another reason for believing that this condition was initiated prior to and present in 1943 is that the average graphite-nodule size of the grossly segregated slip-plane graphitization closely approaches the size of random graphite located in the many specimens of the originally installed material previously examined microscopically. Although growth of isotherm graphite nodules have been followed in several welded joints exhibiting incipient graphitization in 1943, there have been no cases where the rate of nodule growth over a 2-year period would approach that found in this case (assuming this condition to have developed after the original failure).

The depth and direction of the graphite segregation through the pipe wall at section S1 is shown in Fig. 10.

Physical Properties

Several bend and tensile tests were made on pipe sections, the locations of which are shown in Fig. 3. The results obtained are shown in Figs. 11 and 12 and in Table 1. These tests were made principally to confirm the authors' belief that gross segregation of "nodular" graphite whether of the isotherm or slip-plane type is as effective as "chain" graphite in reducing the ductility of low-carbon or low-carbon-molybdenum steel.

The bend test shown in Fig. 11 was removed from section T1 (see Fig. 3). From the location of the fissures it may be noted that this specimen was cut from the upper portion of the quadrant shown in Fig. 6. Although the graphite segregation in this case has no direct relation to the heat-affected zone of a weld, it is to

be carefully noted that its ultimate effect on the ductility of the pipe is similar to that which has been found to occur at the "contact" zone of a welded joint.

Both the side and edge view of a partially pulled tensile bar removed from section J2 is shown in Fig. 12. Planes of graphite may be observed to be "running" at both plus and minus 45 deg on the edge of the machined specimen. The edge view shown was adjacent to the inside pipe surface before removal of the specimen from the pipe. Numerous planes of graphite may be seen to extend from the ID toward the OD in the side view of this specimen. Failure occurred abruptly along one of the graphite planes at a stress of 59,130 psi, followed immediately by a necking-down of the ductile portion of the specimen.

Microscopic Examination

Although macroscopically, slip-plane graphitization as shown in Figs. 4 to 12, inclusive, appears as a continuous crack, microscopically it appears as discontinuous large gray nodules. The relative size and spacing of these nodules determine the resultant ductility of the material.

One of the planes of segregated graphite which was intersected by weld 4-1A in January, 1943, is shown at a magnification of 100 in Fig. 13. It may be seen that the nodules which were outside of the heat-affected zone of the weld remained unchanged, whereas those just within the heat-affected zone were partially put into solution. Those nodules which were in the immediate vicinity of the line of fusion may be seen to be completely dis-

Fig. 13 Intersection of Slip-plane Graphitization With Line of Fusion of Welded Joint 4-1A; ×100

solved by the heat from welding. The sudden solution of the graphite in the austenite, followed by the rapid rejection of the carbon (graphite) as a carbide phase, resulted in the formation of a localized band of steel of hypereutectoid composition. The carbide present in the darkened area in Fig. 13, which is probably in the range of 1 to 2 per cent carbon, can be seen in Fig. 14 to have partially regraphitized in the 2-year period following its inception.

Fig. 14 Partial View of Fig. 13, at Higher Magnification, Showing Structural Detail of Area in Which Graphite Was Redissolved and Reprecipitated as a Carbide Phase During Welding; ×600

The fact that the graphite was put into solution by the heat from the rewelding of joint 4-1A in 1943, is believed to be adequate proof that the graphite was present some time prior to the welding of this joint.

Further proof of this fact is offered in Figs. 15 to 17, inclusive. Slip-plane graphitization at a remote distance from the weld is shown at a magnification of 100 in Fig. 15. The size and detail of these segregated graphite nodules are shown in Fig. 16 at a magnification of 600.

In following the rate of growth of graphite adjacent to welded joints under both actual operating conditions and in accelerated aging tests made in laboratory furnaces, the authors have never encountered a rate of growth of graphite over a 2-year period in low-carbon-molybdenum steel which would even approximate that shown in Figs. 15 and 16.

This is believed to be substantiated by the published work of Kerr and Eberle (3, 6); Smith, Miller, and Brambir (4, 11); Weisberg (5, 12); Hoyt and Williams (7); Van Duzer, McCutchan,

Fig 15 Gross Segregation of Nodular Slip-Plane Graphitization; ×100

Fig. 16 Size and Detail of Graphite Nodules Shown in Fig. 15; ×600

and Rohrig (8, 9); as well as certain unpublished work on this subject by other investigators. In contrast to Figs. 15 and 16, however, the rate of growth of graphite over a 2-year period in the contact zone adjacent to joint 4-2 is shown at a magnification of 600 in Fig. 17. This joint was also rewelded in January, 1943, and it is known that graphite did not exist adjacent to this joint at the time it was rewelded.

Since such a vast difference in nodule size exists between Figs. 16 and 17, it is concluded by the authors that the slip-plane graphitization was initiated prior to 1943, and that the many graphite planes which appear to emanate from the weld are coincidental.

Discussion and Probable Cause of Slip-Plane Graphitization

Owing to the over-all complexity of the graphitization problem as it is known to exist, an attempt has been made to correlate the existing facts with other published information. In so doing

Fig. 17 Growth of Graphite in Regraphitized Joint No. 4-2 After 2 Years of Service; ×600

certain postulations could not be avoided in this discussion.

The iron - iron carbide system, although extremely useful and of real importance to the ferrous metallurgist, has been recognized for many years as a metastable system; the iron-carbon system being the truly stable one. Hoyt and Williams recently stated, "In spite of the apparent stability of iron carbide in the common carbon steels, in which it is the active strengthening and hardening constituent, it has a definite, although usually slight tendency, to change to the more stable form of graphite" (7).

A logical theory regarding the precipitation of carbon (graphite) in steam piping subjected to fluctuating temperatures was presented before this Society in 1944 by F. B. Foley (13). His theory was based upon the slope of the solubility curve of the alpha phase of the iron - iron carbide diagram together with the composition of the alpha phase (ferrite) with respect to aluminum or silicon or both.

It has been shown by Fink and Smith that in precipitation-hardening alloys of the duralumin type, precipitation of the $CuAl_2$ upon aging will always occur preferentially along slip planes resulting from any plastic deformation, before general precipitation occurs (15).

In this respect, it is to be pointed out that the solubility curve for the aluminum-rich solid solution in the aluminum-copper system is qualitatively the same as the solubility curve of the alpha phase in the iron - iron carbide system.

Luders' lines, or "stretcher strains" have been stated by Winlock and Leiter "to occur as a result of the uneven and nonuniform flow of metal at the yield point, caused by the sudden transition of different grains or groups of grain from the elastic to the plastic state." They further state, "Luders' lines occur in the range of deformation corresponding to an elongation of 1.5 to 10 per cent" (16).

On the basis of the foregoing it is believed that slip-plane graphitization is initiated by localized yielding or plastic deformation along slip planes with the formation of Luders' lines or stretcher strains. In the case under discussion major slippage occurred along planes of maximum shear stress. In Fig. 1 it is to be noted that the slip-plane graphitization is located along the pipe length just outside of the 30-deg bend. It is postulated that although this bend was made hot, a sufficient load was applied in making the bend to produce a critical strain (1.5 to 10 per cent elongation) in the cold pipe just outside of the hot-bent region. This bend was subsequently furnace-stress-relieved at 1150 to 1200 F before installation. This temperature was apparently too low to remove the effects of previous strain, in fact it is suggested that the stress-relieving temperature may have initiated actual submicroscopic graphitization along the planes which received localized plastic deformation by virtue of the increased solubility of carbon in alpha iron at the stress-relieving temperature, followed by graphite precipitation upon cooling in accordance with the theory advanced by F. B. Foley.

Just why graphite, or for that matter any precipitating phase should precipitate preferentially along planes which have been plastically deformed is not too clear, although it is suggested by Smith and Brambir that it is due to a greater ease of nucleation of the precipitating phase in the plastically deformed regions (14).

After nucleation of graphite once occurs, its continual growth along either slip planes or isotherms appears quite logical. It is believed, however, that temperature fluctuations in a steam line will result in graphite precipitation only at those locations where a graphite nucleus or a strong graphite nucleating effect is present. It is believed that temperature fluctuations will otherwise result only in the solution and reprecipitation of iron carbide. During this time, however, diffusion of the carbide from the carbide-rich areas toward the ferrite areas, which are low in carbon owing to the slow but continual precipitation of graphite at the graphite nuclei, is taking place.

As the graphite nodules grow in size the surrounding ferrite becomes depleted of carbon. The ferrite around the graphite nodules can therefore only precipitate graphite upon each cooling cycle as fast as the carbon in the alpha iron (ferrite) can diffuse from the carbide-rich areas to the ferrite surrounding the graphite.

Based upon the foregoing assumptions, the rate of graphite precipitation for a given set of temperature conditions would appear to depend upon the number of graphite nuclei present and the rate of diffusion of carbon in alpha iron. This is in general agreement with the postulation made by Smith and Miller who stated, "Conceivably, then, graphite in a limited region could bring about, in time, the substantial depletion of carbide within an entire specimen."

Contrary to the belief or implied belief by many that graphite forms directly from the carbide (Fe_3C) phase due to the higher carbon content of this phase as compared to the alpha phase (ferrite), it is believed by the authors that the mechanism by which graphite precipitation occurs is through the gradual solu-

Fig. 18 Luders' Lines on Back of 8-In. Pipe After Cold-Bending

tion of cementite in ferrite followed by the precipitation of graphite from the ferrite.

As additional evidence that the slip-plane graphite shown in Figs. 4 to 7, inclusive, was nucleated along planes where localized plastic deformation had occurred, Fig. 18 is presented. This illustration was taken from the work of William Hovgaard (17), and was brought to the attention of the authors by Messrs. McCutchan and Crocker, of The Detroit Edison Company. Fig. 18 shows a cold-bent 8-in. pipe which has a stress pattern identical to the slip-plane graphitization pattern shown in Fig. 7. The pattern on the pipe in Fig. 18, however, is formed by Luders' lines which resulted from localized plastic deformation during cold-bending, whereas the pattern shown in Fig. 7 is slip-plane graphitization which was nucleated and grew along Luders' lines which also resulted from a critical amount of plastic deformation during the original bending of this pipe.

Assuming therefore that a material is susceptible to general graphitization, and the service temperature is adequate to obtain graphitization, it is suggested that slip-plane graphitization may be encountered in the following locations of critical strain:

1 Entire bend if the bend was made cold without subsequent full heat-treatment.

2 Cold ends of hot bends if not subjected to subsequent full heat-treatment.

The latter postulation, however, has not as yet been verified, although two bends similar to that shown in Fig. 1 have since been removed for examination.

New Theory Suggested for Nucleation of Graphite at Contact Zone of Welded Joints

It is believed that reasonably good evidence has been presented to show that localized yielding or plastic flow has a strong graphite nucleating effect. Once graphite nuclei have been formed it has been theorized that the graphite will grow through the solution of cementite (Fe_3C) in ferrite, followed by graphite precipitation from the ferrite.

The mechanism of the growth of isotherm graphite formed at the extremity of the heat-affected zone of welds, is believed identical to that of slip-plane graphitization. The condition or agent which causes graphite nucleation at the contact zone adjacent to welded joints, however, has not been too clear. It is now suggested that isotherm graphite is also nucleated by stress, although of a somewhat different nature.

Whereas, slip-plane graphitization is believed to be nucleated by plastic flow from an externally applied load, isotherm graphitization is believed to be nucleated by self-compensated stresses known as "tessellated stresses."

The work of Dr. F. Laszlo on tessellated stress was brought to the attention of the authors by C. H. Davy[4] (18, 19, 20, 21, 22).

Although Dr. Laszlo approaches the subject of tessellated stress mathematically, the following extract which qualitatively defines the subject, is taken from his work: "Anisotropy of the single crystals of most materials and the difference between the bulk physical properties of the components of compound solids readily cause internal self-compensated stress systems to develop around such centers as crystals or components of the compound structure, respectively. These self-compensated stress systems are called tessellated stresses."

One of the first conclusions drawn, after the examination of the pipe failure at the Springdale Power Station, was that the failure occurred at the Widmanstätten grain boundaries at a distance from the weld where the temperature from the welding was

[4] Chief Research Engineer, Babcock & Wilcox, Ltd.

just sufficient to cause grain-boundary transformation.[5] It was also this location where grain-boundary graphite of the "chain" type was located and which was the basic reason for failure.

Just outside of the heat-affected zone the metal structure consists of iron carbide or complex iron-molybdenum carbide, embedded in a matrix of alpha iron (ferrite) whereas, just within the heat-affected zone a portion of the alpha iron goes through a phase change to gamma iron, simultaneously absorbing the carbide phase or as much of it as time will permit under the short heating cycle during welding. Rapid cooling of the heat-affected zone may result in the formation of minute amounts of martensite. There is present in the transition zone (zone of isothermal-graphite formation), therefore, alpha iron which has a body-centered cubic lattice, iron carbide or complex iron-molybdenum carbide which has a complex lattice structure, austenite which has a face-centered cubic lattice, and martensite if formed, which goes through a transition structure of body-centered tetragonal and finally to a body-centered cubic lattice.

Along the transition zone adjacent to a weld, therefore, numerous crystal structures, all of which have their own physical constants and which are surrounded by each other, exist at one time or another during the welding cycle. It is common knowledge that a considerable volume change occurs when alpha iron transforms to gamma iron (austenite) and that upon rapid cooling such as occurs in welding the metal does not go back to its exact original dimensions.

It seems quite reasonable to believe therefore that a system of self-compensated stress is developed around crystals or grains at the transition zone between the heat-affected and unaffected parent metal adjacent to a weld, owing to the different physical constants and directional properties of the several different crystal structures which exist at this location during the welding operation.

It is therefore postulated that graphite is nucleated in the contact zone adjacent to a welded joint by self-compensated stresses known as tessellated stresses.

Summary

1 The term slip-plane graphitization has been chosen to describe a condition of graphite segregation which appears unquestionably to have occurred along slip planes where local yielding or localized plastic deformation had previously occurred.

2 Slip-plane graphitization, unlike isotherm graphitization which has been found to be reasonably uniform through the pipe wall and around the pipe circumference, varies markedly from OD to ID and from quadrant to quadrant around the pipe periphery.

3 Slip plane like isotherm graphitization (if severe) is readily visible to the unaided eye after machining or rough-grinding.

4 Gross segregation of "nodular" graphite, whether of the isotherm or slip-plane type, is as effective as chain graphite in reducing the ductility of low-carbon or low-carbon-molybdenum steel.

5 Substantial evidence has been presented to show that plastic deformation is an excellent nucleating agent for graphite of the slip-plane type.

6 The mechanism of graphite growth of either the isotherm or slip-plane type is believed to occur through the solution of the carbide phase in ferrite, followed by the precipitation of graphite from the ferrite.

7 Having presented evidence to show that slip-plane graphitization is nucleated by stress, the postulation is made that isotherm graphite is also nucleated by stress. In this case, however, a self-compensated stress system is believed to be set up, resulting from the difference in directional properties and physical constants of the several different crystal structures which exist in the transition zone adjacent to a welded joint at the time of welding. Self-compensated stresses of this nature are known as tessellated stresses.

[5] This is known as the lower critical temperature (Ac_1) which is approximately 1350 F for carbon-molybdenum steel.

Acknowledgments

The authors wish to extend their appreciation to Mr. L. E. Hankison, West Penn Power Company, and Mr. G. Sinding Larsen, vice-president, Pittsburgh Piping & Equipment Company, for their co-operation, helpful suggestions, and inspiring influence during the investigation and preparation of this manuscript.

The authors are further indebted to the West Penn Power Company for its permission to publish the results of this investigation.

Graphitization in Some Cast Steels

By A. J. SMITH,[1] J. B. URBAN,[1] AND J. W. BOLTON[1]

Field service and controlled laboratory experiments have demonstrated that it is not possible to insure against graphitization of carbon-molybdenum steel through any of the controlled procedures of melting and deoxidation practice or heat-treatment. It is probable that freedom from graphitization is to be sought through the use of alloy additions which confer greater stability to the carbide. A hypothesis has been put forth concerning the mode of graphitization based upon the observed graphitization behavior of both plain-carbon and carbon-moly steels. Use has been made of this hypothesis to explain the resistance to graphitization of the nickel-chrome-moly steels. The experimental evidence would appear to indicate that the hypothesis is substantially correct.

GRAPHITIZATION characteristics of steels for steam service at elevated temperatures have been a subject of study by many workers since the original failure of a welded carbon-molybdenum steel pipe at the Springdale Station of the West Penn Power Company in January, 1943. Subsequent to that failure graphitization has been found in various classes of wrought and cast products, particularly in weld-affected zones, in the examination of piping systems made by the different power companies.

Happily, the Springdale failure was not disastrous, and to our knowledge none of the other piping systems examined has shown equally extensive graphitization. Nevertheless, it is highly desirable to ascertain means whereby deterioration due to graphitization can be avoided. At the same time it is necessary to preserve in graphitization-resistant material high mechanical properties such as creep strength, soundness, good weldability, and overall economy.

For increasing efficiency in power-plant operation increase in operating temperature is among the promising approaches. Increase to the present 900-950 F has been a development of the past decade. Even now plans are under way for 1000 F operating temperature, and the end of the upswing does not seem in sight. With longer experience acquired as to serviceability of materials at these temperatures, undesirable characteristics have been revealed which hitherto have been unsuspected. From this experience some materials have been shown to be unsuitable for the service. Carbon steel which serves admirably at lower temperatures shows marked loss in mechanical properties at 800 F and is not recommended. Carbon-molybdenum steel which has excellent mechanical properties at 900 to 950 F now is revealed to possess unfortunate graphitization characteristics, limiting its useful application to perhaps 850 F as top operating temperature where welding is a consideration.

In developing and prescribing steels for these higher temperatures, close attention must be paid toward avoiding failures that by chance might occur. All the factors that could contribute to deterioration and failure must be thoroughly investigated. This point is emphasized by occurence of the Springdale failure.

[1] The Lunkenheimer Company, Cincinnati, Ohio.

Contributed by the Joint A.S.T.M.-A.S.M.E. Research Committee on Effect of Temperature on the Properties of Metals and presented at the Annual Meeting, New York, N. Y., Nov. 26–29, 1945, of The American Society of Mechanical Engineers.

The Springdale failure was unexpected. Prior to the failure but one instance of graphitization of low-carbon steel had been reported in the literature (1).[2] Use of molybdenum in steels in high-temperature service led graphitization to be an unsuspected probability since molybdenum is normally considered a relatively strong carbide former and as such likely to promote carbide persistence. There have been arguments for many years on the logic of a double iron-carbon constitutional diagram. Weight of the evidence indicates, however, that iron and graphite are the equilibrium forms, iron carbide or cementite being at best metastable. Since a vast amount of work was required for assuring suitable strength at temperature, possibility of graphitization and other types of structural degradation were neglected.

The Graphitization Problem

The problem of graphitization is complex. It would be quite impossible to study the problem in all of its various phases simultaneously, and it becomes necessary to isolate the various factors and study them individually before any attempt may be made at a comprehensive answer. The problem may be broken down into several subheads, among which are the following:

1 Effects of steel-making practice.
2 Effects of alloying and other elements.
3 Effects of heat-treatment.
4 Effects of fabricating practice.
5 Effects of service operating conditions.
6 Mode of graphitization.
7 Repair of graphitized structures now in service.

Most of the product of the authors' company is in the form of castings. Hence its work in general has been restricted to castings. Certain phases of the foregoing outline have not been touched upon in this work and will be brought up only incidentally. In view of the extensive investigation being carried on by the joint E.E.I. – A.E.I.C. Subcommittee on Graphitization of Piping, no work has been done on possible methods of repair of graphitized structures.

Effect of steel-casting-making practice has been studied here in respect to deoxidation practice.

Fabricating practice, i.e., rolling, upsetting, welding, etc., has not been described in the present report although some work is described on graphitization of structures simulating weld structures.

In the work of the authors' company, some 1300 specimens have been prepared and examined under various conditions of alloy, heat-treatment, and aging-treatment. In this report only those samples will be commented on which were productive of positive evidence in these studies. The others represent duplicate tests for verification of original findings, tests on samples from other heats for the same purpose, cycling tests, etc. The samples chosen for illustration thus should be considered as representing generic classes of structures. The evidence presented for them has been fully corroborated.

Graphitization in Steel Castings

After the Springdale failure many piping systems were examined by the various power companies chiefly by removal of bolt samples from the welded joints. An early discovery of graphiti-

[2] Numbers in parentheses refer to the Bibliography at the end of the paper.

zation in a valve casting led to replacement of the valve in the line so that complete and more leisurely examination could be made. The valve was used as a boiler stop valve at nominal operating temperature of 900 F and was in service a period of 44,137 hr, 1909 of which were 950 F or above, $4^1/_2$ at 1000 F.

The casting had been made in 1936 by the older melting practice of "catching the heat coming down" with partial aluminum deoxidation in the ladle, the remainder in the stream on pouring the mold. Total aluminum added was 1.86 lb per ton.

Analyses were made at several locations. Analyses of inlet and outlet ends were as given in Table 1.

TABLE 1 ANALYSES OF INLET AND OUTLET ENDS OF PIPE

	Inlet, per cent	Outlet, per cent
Total carbon	0.31	0.31
Graphitic carbon	0.12	0.04
Silicon	0.40	0.41
Manganese	0.77	0.76
Phosphorus	0.020	0.021
Nickel	0.11	0.05
Copper	0.05	0.04
Molybdenum	0.42	0.44
Chromium	None	0.01
Aluminum (as Al_2O_3) per cent Al	0.012	0.010
Free aluminum per cent Al	0.017	0.018
Total aluminum per cent Al	0.029	0.028

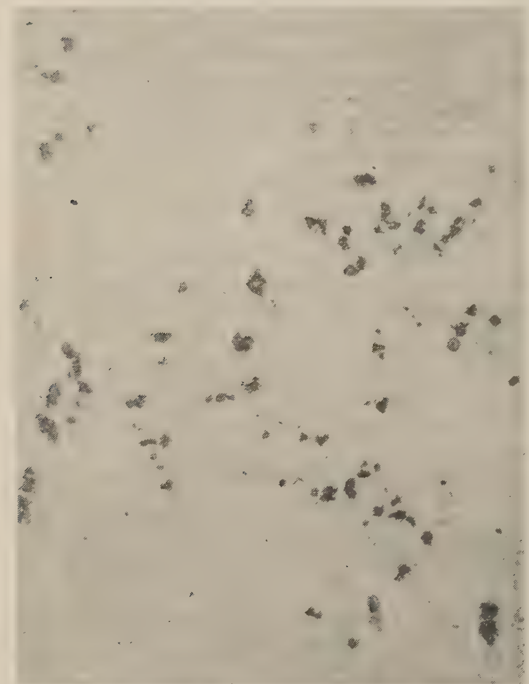

FIG. 1 GRAPHITE IN WELD-AFFECTED ZONE OF CASTING GRAPHITIZED IN SERVICE; ×500

It will be seen that there is no significant difference except in graphite content between the two ends of the valve. Marked visible graphitization had taken place at the inlet end, none could be discovered microscopically in examining several segments of the outlet end. The original cast structure throughout was fine pearlite-ferrite. Graphite in the weld-affected zone was nodular and associated with the carbide areas as shown in Fig. 1.

The wrought-pipe structure was coarse Widmanstäten-ferrite, graphite being similar in amount, type, and distribution to the casting. Just as graphite was not found in the outlet end of the casting neither was it found in the pipe welded thereto. Welding conditions, in so far as they can be judged at this time and presumably as closely as they can be held commercially, were identical.

Service conditions are suspect, yet graphitization was fully reversed in a stop valve from another boiler just adjacent with both high-pressure lines leading to the same manifold. In this other case graphitization was found in the outlet but not in the inlet of both pipe and casting. Truly remarkable circumstances but illustrative of the point that graphitization is in some cases a "hair-trigger" proposition.

Mechanical properties of the graphitized inlet end were investigated, with the finding that there was little impairment of tensile strength and appreciable impairment of elongation and impact. Actual properties were as follows:

Yield strength, psi	57000
Tensile strength, psi	72000
Reduction of area, per cent	54
Elongation, per cent	11.2
Charpy (check tests) ft-lb	7, 9, 6

The tensile bar was made with axis normal to the weld interface, yet the break occurred in the weld metal, not in the graphitized zone. Vee notches in the Charpy bars were placed at the line of graphitization. (Impact value for the base metal of the casting was 18 ft-lb.)

In bend tests made with the bend at the graphitized zone, samples withstood a bend of 90 deg without cracking.

These values show that graphitization has by no means approached the point where it can be considered dangerous, even though it is undesirable. A metal with 6-9 Charpy is hardly "brittle."

Graphitization of Welded Structures

Inasmuch as the Springdale failure was associated with a weld-affected structure, it became incumbent on investigators to include in their agenda of research, studies of this phase of the graphitization problem. Previous extensive studies on welding by the authors' company and others indicated that for an investigation of this type there are too many variables involved for proper assignment of causes of acceleration of graphitization. While normal control of welding insures a commercially desirable result in most cases, absence of exact thermal and composition control leads more to speculation than to scientific fact in considering graphitization rates.

It was evident from our examination and that of others of the Springdale failure that graphitization was most acute in metal which had been raised to the neighborhood of the lower critical temperature. In any work this, then, is a zone of interest. To simulate such structure under closely controlled conditions of temperature, yet free from such influences as composition, gas, slag, etc., present in welds, standard bars ($^7/_8$ in. round × 6 in. long) were heated at one end in a bath at 1600 F, the other end at 600 F, and after holding at temperature 1 hr the bars were quenched. Hardness surveys were then made to determine the critical zones, whereupon the bars were placed in aging furnaces at 975 F, 1025 F, and 1100 F. Graphitization was found to be most rapid at 1100 F, very slow at 975 F, hence 975 F was discontinued as an aging temperature.

In steels prone to graphitization, graphite appeared first in the critical zone, subsequently appearing in the zone quenched from a higher temperature, and later in the zone quenched from a lower temperature. From this it would appear that welding, *per se*, is not responsible for the severe graphitization in the weld-affected zone, but that this condition is induced by heating the material to perhaps just above the critical followed by rapid cooling. To verify this point several samples were heated to various temperatures

Fig. 2 Graphitization in Carbon-Moly Steel After 500 Hr at 1100 F in Sample, Quenched From 1390 F; ×1000

within this critical range. Graphitization was found to occur most rapidly in samples heated to 1390 F and water-quenched, appearing extensively as early as 500 hr at 1100 F. Time of heating these samples at 1390 F was 3 hr. Graphitization as it appears is shown in Fig. 2.

Welding and its effects on graphitization in piping systems are not to be set aside briefly. However, simple one-bead welds, or restriction to a single set of welding conditions are likely to lead to unsound conclusions. Precise time-temperature conditions (at given locations) and other variables are neither known nor controllable in usual welding techniques. This means that welding studies, to be safely useful, must include many variations in welding practices, hence must be voluminous in respect to experimental manipulations. Extensive investigation is under way to study its full bearing on the problem, the results of which it is hoped will be presented at an early date.

If heating to a zone in the neighborhood of 1390 F (for carbon-molybdenum steels) is critical for promotion of graphitization, as is indicated by the foregoing experiments, and the time at this temperature is not too significant, as the experiments also suggest, then any method of differential heating (welding or other) will produce a zone critical for graphitization. This would call for viewing with caution any method designed to offset the effects of welded structures such as have been proposed, for example, austenitic welding, postnormalizing, etc. Such procedures might serve merely to move the zone to a different location without certain amelioration.

Effects of Deoxidation Practice and Heat-Treatment on Graphitization Tendencies

Certain studies were carried out to ascertain some of the effects of silicon and silicon-aluminum deoxidation and of various structures and treatments on the graphitization tendency of carbon (A.S.T.M. A-216-WC-B), carbon-molybdenum (A.S.T.M. A-217-WC-1), and nickel-chrome-moly (A.S.T.M. A 217-WC-4) steels.

Steels were made up according to regular commercial practice, i.e., $2^1/_2$-ton charges in acid electric furnace. Practice includes ore addition and boil, followed by recarburization and furnace deoxidation by ferrosilicon, ferromanganese, and silicomanganese. Before pouring, tests of such metal lie quietly due to the "silicon deoxidation." ("Silicon-deoxidized" samples were taken at this period.)

When the steel is poured into a large ladle, aluminum is plunged in, 2.4 lb per ton being used. Samples taken therefrom are referred to as "silicon-aluminum-deoxidized."

All samples received a normalize after 5 hr at 1650 F, and were drawn for 5 hr at 1200 F, before subsequent experimentation.

Compositions and room-temperature mechanical test properties of the steels referred to are given in Table 2.

Carbon Steel— WC-B (Heat A). Samples, silicon-aluminum-deoxidized, were heated 3 hr at 1550 F, and quenched into molten tin at 1300 F, at which temperature they were held for 30 sec, 2 min, 20 min, 2 hr, and 5 hr, followed by water-quenching. A complete range of structures was developed, from martensite to lamellar pearlite. Substantial amounts of proeutectoid ferrite were evident in all samples. A comparison sample quenched directly into water from 1550 F, yielded a martensitic structure with small amounts of proeutectoid ferrite appearing only in the boundaries of the original dendrites.

Aging 2000 hr at 1100 F produced full spheroidization, of about the same particle size, and graphitization, to about the same degree, in all samples.

Carbon Steel—Heat B. This metal was divided into silicon-deoxidized and silicon-aluminum-deoxidized portions. A series of isothermal quenching treatments was performed on samples of both coarse and fine austenitic grain size. Coarsening temperature was 1900 F, followed by furnace-cooling to 1550 F, and quenching. Refining was carried out by heating to 1550 F, followed by direct quenching. Quenching was carried out in a controlled tin bath.

Temperatures employed were those used in earlier work on car-

bon-molybdenum steel (4) and which gave the structures for carbon moly shown in Table 3.

TABLE 3 CARBON-MOLYBDENUM STEEL STRUCTURES, HEAT B

	Structure (carbon moly)	Transformation temperature, deg F
I	Coarse pearlitic	1200
II	Coarse mixed pearlitic-acicular	1000
III	Coarse acicular	800
IV	Coarse martensitic	500
V	Fine pearlitic	1200
VI	Fine mixed pearlitic-acicular	1000
VII	Fine acicular	800
VIII	Fine martensitic	500

The acicular structure of the carbon-moly steels is not a member of the plain-carbon-steel series, hence was not developed in this experiment. Also it was not possible to develop a martensitic structure at 500 F in this carbon steel. However, since we are more concerned with comparative temperature levels in processing these materials than in the actual structures, it was thought desirable to retain the quenching-bath temperatures used earlier and on which fairly complete data were available.

TABLE 4 CARBON-STEEL STRUCTURES

	Structure (carbon steel)	Transformation temperature, deg F
I	Coarse pearlitic	1200
II	Coarse mixed pearlitic-bainitic	1000
III	Coarse upper bainitic	800
IV	Coarse lower bainitic	500
V	Fine pearlitic	1200
VI	Fine mixed pearlitic-bainitic	1000
VII	Fine upper bainitic	800
VIII	Fine lower bainitic	500

In the carbon steels Table 4 gives the structures approached. The structures shown in Figs. 3 to 6 respectively, are of the coarse series, and it may be seen that they do not correspond in all respects to the type description. This is because of the difficulty of securing a homogeneous austenite in cast materials. Because of these inhomogeneities there was marked separation of proeutectoid ferrite similar to that developed in conventional heat-treatment of castings. This alters the effective carbon concentration in the carbide areas and affects the time of reaction at a given temperature.

All of the silicon-aluminum-deoxidized samples graphitized within 1000 hr at 1100 F. Graphitization was most general in the type VIII sample (fine lower bainite). Size of graphite particles was about the same in all samples.

Of the silicon-deoxidized samples the following graphitized at 1100 F within the time indicated:

I	Coarse pearlitic	2000 hr
II	Fine pearlitic	6000 hr
VII	Fine upper bainitic	4000 hr

The following were resistant for the duration of the test, 6000 hr:

II Coarse mixed pearlitic bainitic
III Coarse upper bainitic
IV Coarse lower bainitic
VI Fine mixed pearlitic-bainitic
VIII Fine lower bainitic

The foregoing suggests that fine and uniform distribution of carbide may lessen initial graphitization tendency. Since such distribution indicates less steep carbon-concentration gradients, such influence might be expected, at least in initiation of the reaction. However, once action is started, a more general nucleation might well cause more general graphitization.

In case of this carbon steel, silicon-aluminum deoxidation favors graphitization, but the absence of aluminum does not always prevent it.

The two deoxidation practices influence hardenability, silicon deoxidation tending toward coarser grain and deeper hardening. Since bainitic structure in silicon deoxidized graphitized, the effects of differences in hardenability characteristics (as influenc-

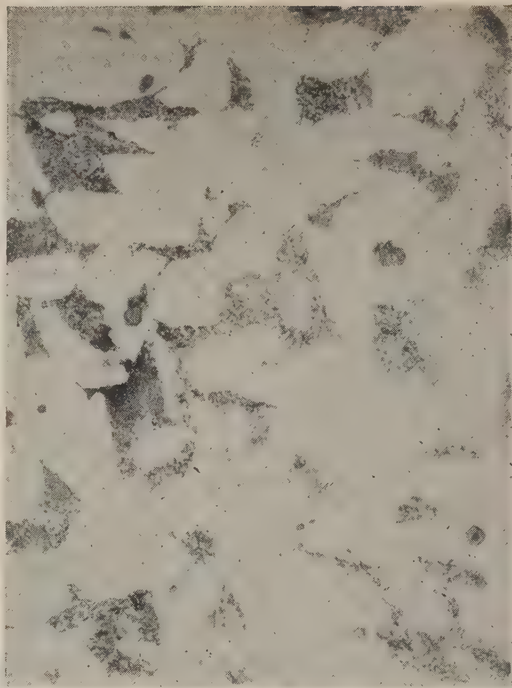

Fig. 3 Coarse Pearlitic Carbon Steel: ×500

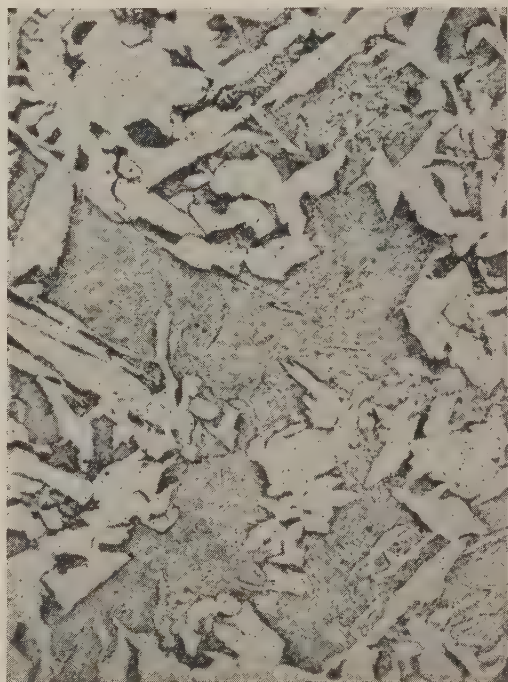

Fig. 4 Coarse Mixed Pearlitic Bainitic Carbon Steel; ×500

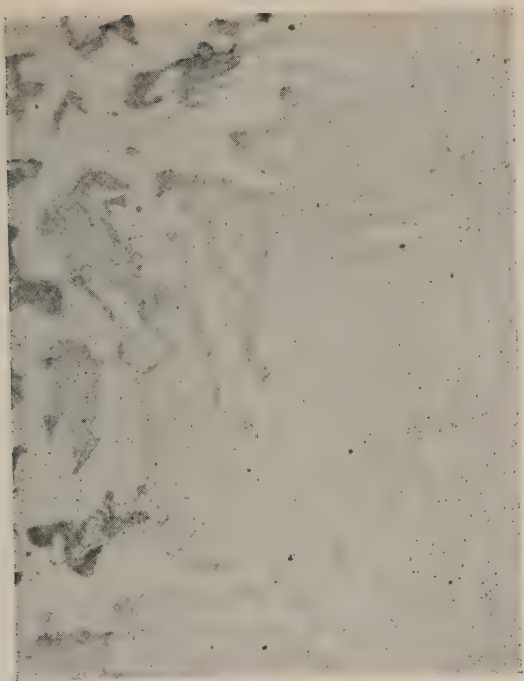

FIG. 5 COARSE UPPER BAINITIC CARBON STEEL; ×500

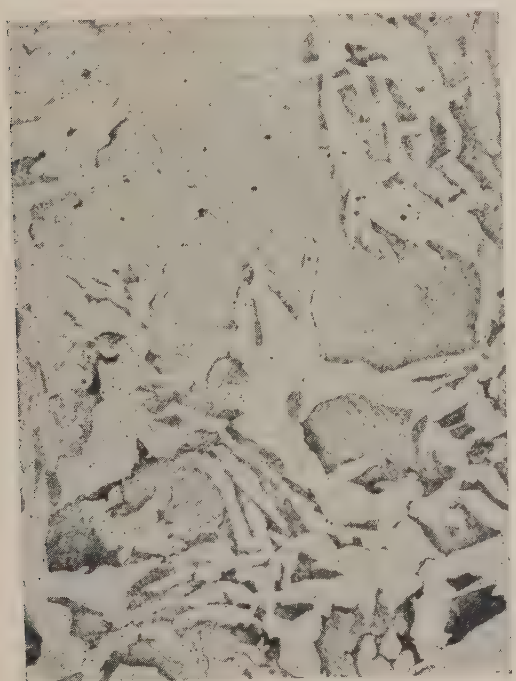

FIG. 6 COARSE LOWER BAINITIC CARBON STEEL; ×500

ing graphitization) may be somewhat discounted. However, a number of these points require more extensive study before firm generalities can be safely made. Subject to this qualification, the experimental work on carbon steel (WC-B) suggests the following:

(a) Silicon kill retards graphitization tendency, but does not safely prevent it.

(b) Carbon-concentration gradients appear to promote the earlier formation of graphite.

(c) Greater carbon homogeneity may promote more general graphitization, once the reaction is initiated.

(d) Coarser austenitic grain and deeper hardening characteristics tend toward greater resistance, but may not assure it. (This might well be independent of agencies promoting such structure.)

Conventional normalize and anneal, under production conditions permitted graphitization in both silicon and silicon-aluminum-deoxidized conditions. Silicon-aluminum deoxidized graphitized in less than 4000 hr; silicon deoxidized in 6000 hr.

Principal structures aged at 1100 F were aged in duplicate at 1025 F. Of the silicon-aluminum deoxidized all had graphitized at 1000 hr, with the exception of the mixed pearlitic-bainitic, again showing the resistance of this structure to graphitization. Otherwise little difference was to be noted from 1100 F aging.

Carbon Moly (WC-1) Steel (Heat C). This material was divided into silicon-deoxidized and silicon-aluminum-deoxidized portions. Samples were put into the following structural conditions, and graphitization time as it appeared in the silicon-aluminum deoxidized samples which developed graphite within 6000 hr is as given in Table 5.

TABLE 5 CARBON-MOLYBDENUM STRUCTURES; HEAT C

Structure (carbon moly)	Graphitization
Coarse pearlitic	2000 hr
Coarse-pearlitic-acicular	None
Coarse acicular	2000 hr
Coarse martensitic	None
Fine pearlitic	6000 hr
Fine pearlitic-acicular	None
Fine acicular	None
Fine martensitic	None

In these structures there was considerable separation of proeutectoid ferrite leaving the carbides as islands in a ferritic ground mass. This appears to be the common pattern developed in carbon-moly steels. In looking for graphitization such structures are suspect. On the other hand, the structure description describes the state of aggregation of the carbide to much better degree than was found for the carbon steels.

No graphitization was found in the corresponding silicon-deoxidized samples, within 6000 hr.

The grain size for the silicon-deoxidized portion was 2-3 with normal McQuaid-Ehn as shown in Fig. 7.

In heat D, silicon-aluminum, killed, similar samples all graphitized within 6000 hr or less. Grain size and normality were similar for both silicon-aluminum-killed heats, i.e., 6-7 and markedly abnormal McQuaid-Ehn, Fig. 8.

Production heat-treatment of normalize from 1650 F yielded graphitization within 2000 hr in the silicon-aluminum-deoxidized, none within 6000 hr in the silicon-deoxidized. However, graphitization was found in 6000 hr in a silicon-deoxidized sample held 5 hr at 1650 F, and furnace-cooled as shown in Fig. 9. The sample illustrated is the only one that has been developed experimentally in our work showing an approach to chain graphite. All others have been nodular. The correspondingly treated silicon-aluminum-deoxidized sample showed nodular graphite.

The results on carbon moly (WC-1) indicate that silicon deoxidation resulting in coarse-grain normal McQuaid-Ehn structures retards graphitization, but does not always prevent it, as was established also in case of carbon (WC-B) steel. It is apparent that as compared with carbon steel the molybdenum content of WC-1 increases carbide persistence.

In another experiment on a silicon-aluminum-deoxidized sample, heat C was held 5 hr at 1650 F and furnace-cooled, then

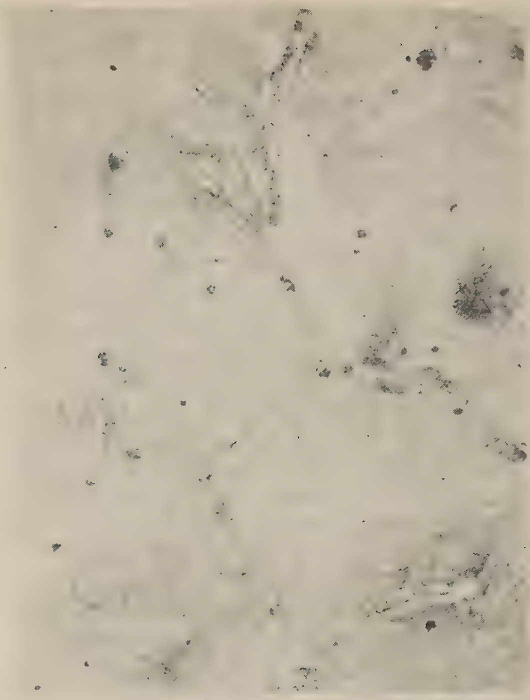

Fig. 7 McQuaid-Ehn Case Heat C Silicon Deoxidized; ×500

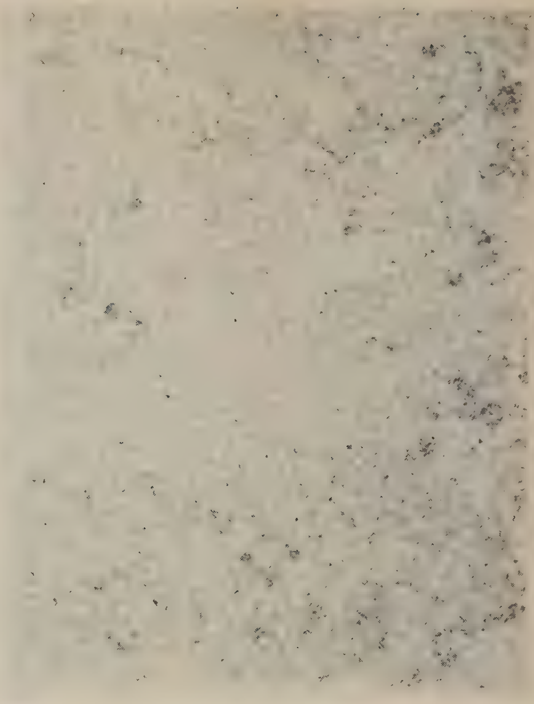

Fig. 8 McQuaid-Ehn Case Heat C Silicon-Aluminum Deoxidized; ×500

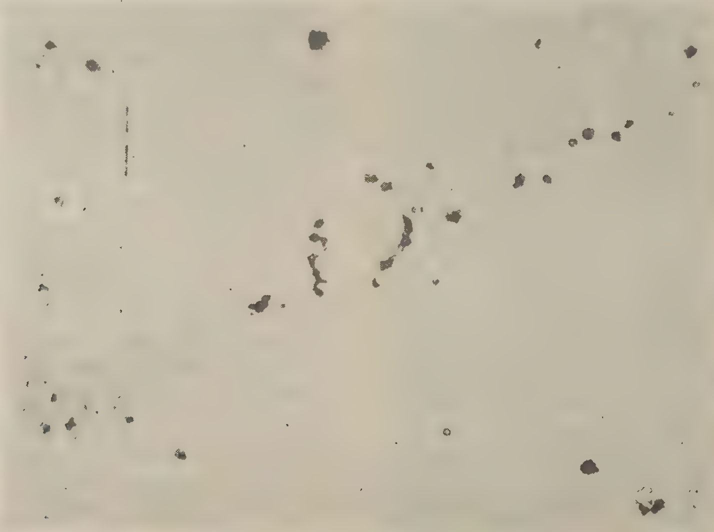

Fig. 9 Graphitization in Silicon-Deoxidized, Heat C; ×500

drawn for 10 hr at 1300 F; graphitization being produced within 4000 hr at exposure to both 1025 and 1100 F.

This treatment was employed to determine the effectiveness of high-temperature annealing in order to stabilize the carbides in somewhat different form as suggested by Smith and Miller (5).

Consideration of these and other studies, and of the published literature and field data, indicates that carbide persistence is influenced by many variables; some whose general influence seems clear, others which must be better known and evaluated before conclusions can be drawn.

Since strength at temperature is fully as important as structural stability, creep tests were run at 950 F on samples from heat D, heated for prolonged periods at the suggested stabilizing temperature, i.e., 110 hr at 1320 F, after normalizing from heating at

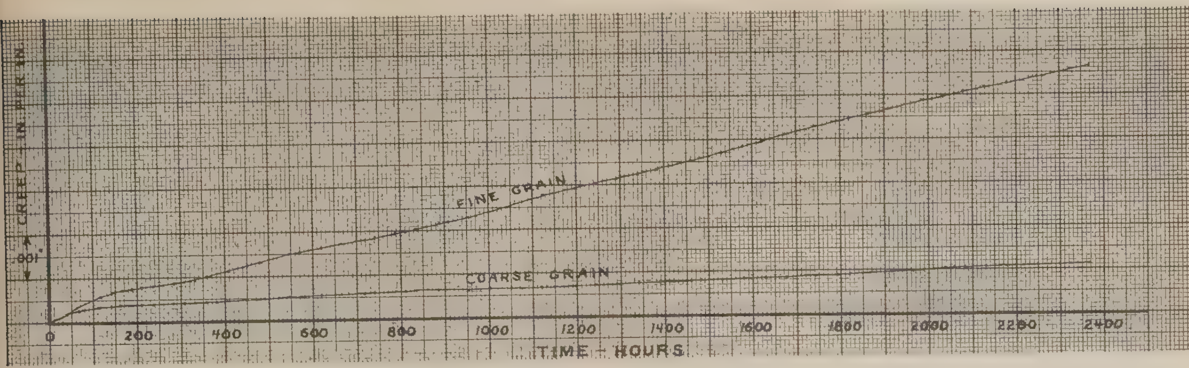

FIG. 10 CREEP CURVES FOR CAST CMO STEEL

1550 F in one case and from heating at 2200 F, followed by furnace-cooling to 1550 F in another to yield both fine- and coarse-grained structures in a highly spheroidized condition. The resulting creep curves are shown in Fig. 10. Tests were carried out for a period of 2400 hr under loads of 12,000 psi. In both cases graphitization was found after test. The test temperature of 950 F was the lowest at which graphitization has been produced in this laboratory. At least in this steel, treatment at 1320 F has not insured against graphitization. Structures of the samples before and after test are shown in Figs. 11 to 14, inclusive.[3]

Nickel-Chrome Moly (WC-4) Steel. Samples of silicon-deoxidized and silicon-aluminum-deoxidized metal, heat E, were prepared. Each series was placed in the eight structural conditions listed for carbon moly (WC-1) given previously. After exposures to a maximum of 6000 hr at 1100 F, no graphization appeared in any sample.

In another series of experiments on a silicon-aluminum-deoxidized heat, heat F, with samples placed in the same structural condition, no graphite was found after 7976 hr at 1100 F. Duplicate experiments at 1025 F also failed to reveal any evidence of graphite development.

As in the carbon-moly steels, creep tests on nickel-chrome-moly steel were carried out with identical prior heat-treatment including commercial normalize and draw conditions. No graphitization was found in the bars after test. Structures before and after testing were as shown in Figs. 15 to 18, inclusive.

It will be noted that a number of the structural and deoxidation conditions in which WC-4 was placed correspond to those in which

[3] "Coarsened" means coarsened austenitic grain size. This treatment results in greater carbon homogeneity. Thus the resulting transformation product aggregations (Figs. 11 to 14, inclusive) give appearance of finer "grain" in the coarsened sample photomicrographs. There is no anomaly. The reader is cautioned not to confuse "pearlitic" grain-size appearance with austenitic grain which is not shown.

rapid graphitization was found in carbon-moly (WC-1) steel. Work on WC-4 was confirmed by study of several heats. (Differential quench samples also showed no graphitization.)

Mode of Graphitization

Emerson (6) has distinguished between two types of graphite formation, "nodular" and "chain." Our study suggests the desirability of including a third type, "flake," a formation shown in Fig. 19. Graphite formations and groupings in reality are in three dimensions, not two, as they appear in a photomicrograph. This must be borne in mind in any attempt to evaluate apparent orientations in respect to their evolution and effects.

Emerson (6) has illustrated the chain formation in such a way as to leave little doubt as to its distribution and possible conse-

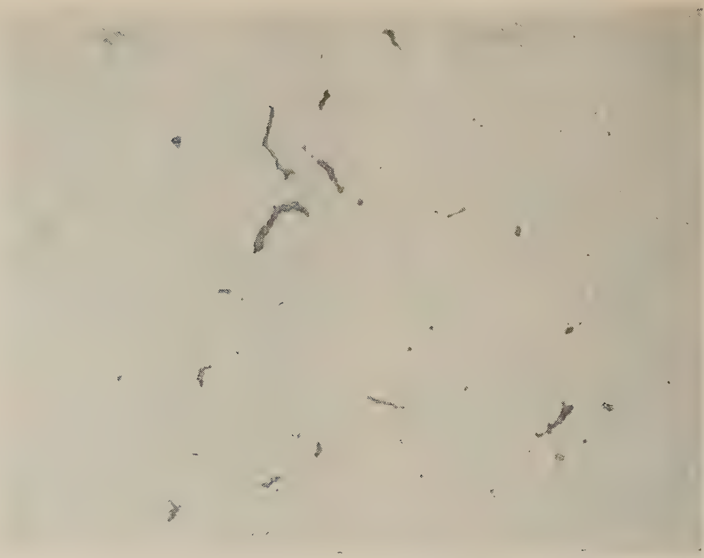

Fig. 20 Casting as Removed From Service; ×500

quence. A flake may be but a progressive development of a chain although our studies suggest otherwise.

For the purpose of identifying graphite, polarized light has been very useful. Graphite crystallizes in the hexagonal system and shows extreme pleochroism and birefringence in polished section (7). Using a first-order red compensator plate, the change from red to green with stage rotation is striking and distinctive. This and other characteristics of graphite have been observed before in this laboratory in the course of its studies on cast iron. Hence the tool fits very nicely into investigations of graphitization in steel.

The color change at extinction for a particular crystal depends, among other factors, on its orientation with respect to the plane of polarization of the light. Differently oriented anisotropic crystals will show extinction at different angles of stage rotation. Nodular graphite shows a mottling of red and green with a first-order red compensator. This indicates that it is formed of many small crystallites of various orientations. However, in many of the graphite formations described as flake, uniform extinction of the whole flake was shown at the same angle. This was evident in the flakes shown in Fig. 19. This suggests that the formation is of uniform crystal orientation and is of the character of a single crystal, bearing close similarity to the flakes found in cast iron. The massive portion attached to one of the flakes of Fig. 19 shows the mottled effect and is definitely polycrystalline. This sample was from a segment of pipe removed from service and given a cycling treatment for 800 hr between 950 F and 1100 F. Fig. 20 is from a sample taken from a casting as removed from service. It also shows the single crystal or flake behavior.

Were these flakes built up from a chain it is improbable that there would be crystallographic uniformity along the whole chain. The Widmanstätten relationship which exists between matching planes of precipitate and matrix can be met in several different ways with respect to the plane of polish, so there is no requirement that all graphite particles separating from a single ferrite grain should have the same orientation with respect to the plane of polish even though the growth mechanisms are identical. Thus a plate of graphite built up from a series of particles originally in chain form would be expected to be broken up crystallographically into a number of segments which would be clearly revealed by examination in polarized light.

There is one point of similarity between flake and chain formation which seems significant in attempting to explain the mode of graphitization. As shown in Figs. 19 and 20, in Emerson's illustrations of chain formation (6), and also in certain of the illustrations of Weisberg (8) and Kerr and Eberle (9), graphite in these instances is located in the ferrite grain boundaries. Nodular graphite usually is associated with the carbide areas. While chain and flake graphite may be attached to carbide areas, perhaps at other locations than the plane of polish, the formations extend out into regions of primary ferrite.

The general mechanism of graphite formation involves two steps, i.e, formation of a nucleus or initial graphite particle, and growth of the particle by diffusion of carbon to it.

The first step necessitates a local concentration of carbon together with some nuclear influence. The nuclear influence may be developed in many ways, submicroscopic impurities or other discontinuities probably playing a major role. A grosser sort is illustrated in Fig. 14 where a graphite flake is seen radiating from a manganese-sulphide inclusion. The second step requires diffusion of carbon toward the first formed particles from carbides or from other graphite particles less capable of sustained growth. As the region about the growing particle becomes depleted in carbon, migration through the ferrite occurs. Ferrite dissolves a certain amount of carbon (varying with temperature) and local depletion in one area results in carbon diffusion from another, thus maintaining a statistical balance. The diffusion distance is extreme in some cases as in the chain or flake graphite lying at some distance from the carbide "reservoirs."

Thus there are two approaches in the problem of preventing deterioration: Promotion of relative carbide stability; and the lessening of the possibility of diffusion of carbon through ferrite.[4]

Other factors being equal, tendency toward graphitization in the iron-carbon series increases with increasing carbon content. Hypereutectic cast irons (with primary cementite) graphitize in the freezing range with the formation of kish or free graphite in the partly liquid metal. The gray irons graphitize rapidly in the

[4] "Stability," as used in this paper implies resistance to breakdown over a normally expected service life. It is not possible to say that any carbide is stable in the true equilibrium sense. However, the term is descriptive when used in its practical sense.

interval between the eutectic and eutectoid temperatures. This graphitization may continue even below the eutectoid under slow-cooling conditions or in the presence of sufficient silicon.

In the case of malleable iron, the composition is so chosen that there is no graphitic carbon as cast. Subsequent treatment is such that the cementite is graphitized both above and below the eutectoid-transformation range. The mechanism of carbon diffusion through the ferrite toward graphite particles is perhaps most vividly shown by the formation of "bull's eyes," graphite particles surrounded with ferrite in a general pearlitic matrix.

Graphitic steel is a product of commerce. Austin's work (10) shows how readily high-carbon steel can be graphitized in quite a short time.

In normal carbide areas the concentration of carbon is high, well above that of the average for the whole sample. As more and more proeutectoid ferrite is present in a given analysis, it is readily seen that the carbon concentration in the carbide areas becomes much greater, ultimately approaching the eutectoid composition. With such concentration gradients a graphitizable steel will usually graphitize most readily regardless of state of aggregation of carbide. Thus steels with large areas of free ferrite are more suspect for serious graphitization than steels of a more homogeneous character even though the more homogeneous steels may ultimately graphitize.

The problem of stabilizing the carbide and preventing diffusion in ferrite is complex but its solution is necessary for insuring against service failures due to graphitization. All of the carbide formers have a solubility in ferrite and under proper circumstances may dissolve even when carbon is present, e.g., in the presence of a stronger carbide former. In a straight molybdenum steel the molybdenum undoubtedly is associated in large measure with the carbide. Hence with little distortion of the ferrite lattice, the interstitially dissolved carbon is able to diffuse at will. The binding forces of the molybdenum are evidently satisfied fully as well in an iron-molybdenum carbide as in a straight molybdenum carbide with the result that carbon can be given up by the molybdenum to be subsequently precipitated as graphite by the ferrite without too greatly altering the state of free energy of the system.

Although good creep properties have been shown for carbon-free iron-molybdenum alloys (11) in the normal steels, molybdenum is depended upon for conferring strength at elevated temperatures in the formation and distribution of a stable and resistant carbide. Yet it is known that certain amounts are dissolved in the ferrite. In a higher-carbon steel, 0.70 carbon, Bowman, Parke, and Herzig (12) have shown the amount in the ferrite to be of fairly low order, possibly less than 20 per cent of the total. Partition data on steels such as described in this report, are not available. It may be reasoned, however, that the partition coefficient would be changed with composition and with lower carbons more molybdenum would dissolve in the ferrite. Carbon-molybdenum steel castings for ET service contain some 30 to 50 per cent more carbon than carbon-moly piping, and hypothetically, the partitionment of molybdenum in ferrite in the piping would be greater than in the castings. Yet the piping materials graphitized perhaps more readily than the castings, at least such appears to be the case from the service record. This suggests that increasing molybdenum dissolved in ferrite would not bring about assurance of freedom from graphitization.

Creep properties at elevated temperatures are markedly altered by carbide pattern and distribution. Hence it would appear that the superior creep properties of molybdenum-bearing steels are dependent in large part upon the molybdenum or iron-molybdenum carbide and are not to be sought in steels alloyed with stronger carbide formers in which the molybdenum would be forced to much greater extent into the ferrite, leaving the new alloying element, such as vanadium or titanium, to form the principal carbides. Such steels have not been shown to possess superior elevated-temperature properties in the absence of molybdenum and improve molybdenum steels to but minor extent. Thus such carbides cannot be looked on as a source of strength at such temperatures.

To protect against graphitization by use of alloys it appears that greater success might be achieved by use of weaker carbide formers than molybdenum or by noncarbide formers, which would dissolve in the ferrite and force more molybdenum into the carbide. By distortion of the iron lattice with dissolved elements, diffusion is interfered with and at the same time the ferrite is strengthened. The molybdenum being forced further into the carbide should confer additional elevated temperature strength to the carbide. Copper, cobalt, and nickel do not form carbides and might be found to perform this particular function. Chromium would show similar behavior since, although a carbide former, it is weaker in this respect than molybdenum. It is probable that combinations of these would be of more effect than when used singly, in accordance with general knowledge of the behavior of alloying elements.

The foregoing reasoning is hypothetical. Partition data are not as yet available by which the hypothesis can be fully evaluated. However, behavior of steels of the type of WC-4, nickel-chrome-moly lends substantiation to its correctness. This steel could not be graphitized under any set of conditions in the laboratory and has not graphitized in service.

Furthermore, it has creep properties superior to carbon-moly steel as is indicated by the various creep studies. Creep tests with various comparable structures confirm this. (They are not a part of this report since they in themselves have little bearing on the graphitization problem.) The nickel may play an important part in this stabilization or it may be looked upon more as a safety measure since, not being a carbide former, it opposes ferrite solution of the other elements but would not in itself be partitioned. The finding by Smith, Miller, and Tarr (13) that a molybdenum steel containing 0.17 chromium was readily graphitizable and by Hoyt (14) that a 0.50 chromium steel could be graphitized leads to some question whether steels containing this chromium alone (as has been proposed) would provide complete assurance against graphitization. It remains for subsequent work to demonstrate conclusively whether or not such additions can be relied on for this purpose, over a wide range of manufacturing, fabrication, and operating conditions.

Discussion of Results of Studies

While the Springdale failure was disconcerting, possibilities of graphitization probably should not have been unexpected. In the high-carbon steels the problem had been studied rather extensively, especially by Austin and co-workers. A failure in straight low-carbon steel also had been observed under quite similar circumstances.

In detection of early stages of graphitization the most useful tool is the microscope. To observe graphite in a polished section a special technique is involved for its retention in the section, the graphite being readily removed in the the normal polishing operation. Undoubtedly, were graphite present it would have been preserved with inclusion polishing. However, inclusions almost invariably are studied before extended heat-treatment rather than after. This probably accounts for graphite not being detected even in creep samples until its presence was suspected.

The major question that arises is whether or not any carbide is stable under all conditions of temperature and pressure. It is entirely possible that none is, ultimately; yet certain carbides may prove sufficiently persistent to endure for the expected service life of the parts without undue deterioration.

It is not known what conditions are required for carbide stability. Molybdenum is normally considered a strong carbide former yet failure took place in a molybdenum-bearing steel. Chromium is less strong as a carbide former than molybdenum yet a nickel-chrome-moly steel proved quite resistant to graphitization experimentally and evidence from field service supports the laboratory findings. Results of others suggest that sufficient percentages of chromium likewise might be proved effective. The hypothesis has been advanced in the present paper that ferrite plays an active part at least in chain or flake graphitization. It must play a part in nodular graphitization also. If this hypothesis is correct, then an explanation of the stability of the nickel-chrome-moly steel may be found in the fact that the nickel is dissolved in the ferrite, and, with a stronger carbide former, molybdenum, being present than the chromium, the chromium likewise is largely dissolved in the ferrite, resulting in the conferring of stability to the ferrite against carbon rejection in the form of graphite.

It is believed that if a steel initially is seriously unstable from its composition, no amount of "doctoring" will insure sufficient stability for prolonged service. Thus production of a straight carbon-moly steel of coarse grain size and normal McQuaid-Ehn structure is not sufficient to prevent graphitization over normal service periods although the graphitization rate may be very considerably slower or its initiation require more unfavorable fabricating and operating conditions. A desirable initial structure likewise may retard but will not insure against graphitization. This has been shown not only for different distribution of constituents but also for their constitution, as, contrary to the suggestion of some workers, steels annealed at temperatures which would promote formation of a presumably more stable molybdenum carbide subsequently graphitized at lower temperatures.

It appears also that little is to be safely hoped for by modification of weld practice short of normalizing the whole assembly before installation since any type of localized heating will result in some zone being heated into the temperature range critical for graphitization.

Thus far, critical field graphitization has been found adjacent to welds. In many instances, however, noncritical graphitization has been found elsewhere in piping and castings. In no case that has come to the authors' attention has graphitization proceeded as far as at Springdale. Thus it is perhaps fortuitous that critical graphitization has not been found in regions not associated with welds. The recent finding at Springdale of graphite precipitated on slip planes well removed from a weld leads to suspicion that finding of such critical graphitization may be made in the not too remote future.

The use of alloys for stabilization appears to offer the most promising hope against such a condition. As indicated, it may be as fully necessary to stabilize the ferrite as to stabilize the carbide. Both laboratory and field experience appear to indicate that a steel conforming to A.S.T.M. A-217-WC-4 is an approach in this direction.

Summary

From many samples studied both from field service and controlled laboratory experiment it has not been shown possible to insure against graphitization of carbon-molybdenum steel through any of the controlled procedures of melting and deoxidation practice or heat-treatment. The evidence would appear to indicate that freedom from graphitization is to be sought through the use of alloy additions which confer greater stability to the carbide. Cases cited in the literature of graphitization of low-alloy chrome-molybdenum steel at conventional service temperatures lead to little assurance of freedom from graphitization over the normal service life by the use of such low chromium additions to the moly steels alone. Critical percentage ranges, if existent, should be revealed by co-operative work being undertaken by various agencies. Extensive experimental data lead to such assurance for the nickel-chrome-moly steels within the present specification range of A.S.T.M. A-217-WC-4. Experiments with carbon-moly steel have been duplicated for the most part with nickel-chrome-moly steel with special reference to those conditions which are critical for carbon-moly steel, silicon-aluminum kill resulting in a highly abnormal steel structure. In no case has graphitization been found in the nickel-chrome-moly steel.

A hypothesis has been put forth concerning the mode of graphitization based on the observed graphitization behavior of both plain-carbon and carbon-moly steels. Use has been made of this hypothesis to explain the resistance to graphitization of the nickel-chrome-moly steels. The experimental evidence would appear to indicate that the hypothesis is substantially correct.

Discussion

F. Eberle.[5] One of the most important facts developed in this paper is the experimental evidence of the fundamental instability and, incidentally, also of the relatively great stability of straight silicon-killed McQuaid-Ehn coarse-grained and normal carbon-molybdenum steels. At 975 F, which may be considered as an upper temperature limit for the use of this steel in steam-

[5] Research Metallurgical Engineer, The Babcock & Wilcox Company, Barberton, Ohio.

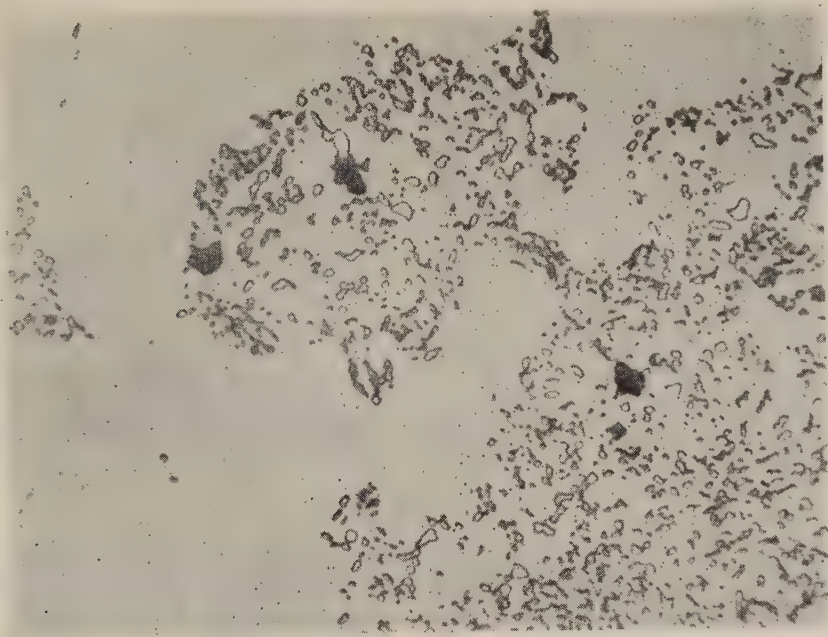

FIG. 21 LOW-TEMPERATURE END OF WELD-AFFECTED ZONE IN CREEP-TEST SPECIMEN CASE 3; ×2000

plant operation, the authors found the rate of graphitization to be very slow and therefore they conducted most of their experiments at 1100 F. Even at this extreme and impractical temperature only one out of the described ten test samples of straight silicon-killed carbon-molybdenum steel produced graphite within 6000 hr. The sample which did graphitize had been in the 1650 F-furnace-cooled condition in which the steel is most susceptible to graphitization.

As a further illustration of the fundamental instability and the relatively great stability of McQuaid-Ehn normal carbon-molybdenum steel, we present the following results of tests and examinations conducted in the laboratory of the writer's company:

Case 1. A creep-rupture specimen containing a 1200 F, stress-relieved, standard, multiple-pass arc weld in the center of the gage length was found free of graphite after 11,400 hr at 950 F under 20,000 psi which is $2^1/_2$ times the allowable working stress. The steel was silicon-aluminum-deoxidized (0.75 lb. of aluminum per ton) and was McQuaid-Ehn normal- and medium-grained (grain size No. 6). Prior to the welding the steel had been normalized at 1650 F.

Case 2. A creep-test specimen made of 1650 F normalized unwelded silicon-aluminum-killed carbon-molybdenum steel (0.5 lb. of aluminum per ton) also was found free of graphite after 8380 hr at 950 F under 10,000 psi which is $1^1/_4$ times the permissible working stress. This steel, too, was McQuaid-Ehn normal- and medium-grained (grain size No. 4-5 with some No. 6).

Case 3. A creep-test specimen made of the same material as previously described (case 2), but containing a standard multiple-pass arc weld, stress-relieved at 1200 F, in the center of the gage length, was found to contain a very few tiny graphite nodules in the low-temperature end of the weld-affected metal after 8380 hr at 950 F under 10,000 psi which again is $1^1/_4$ times the allowable working stress. These graphite nodules were so small that they could be recognized only at very high magnification and then identification was not absolutely assured (see Fig. 21 of this discussion).

Case 4. Another creep-test specimen, again made of the same material as used for the last described two samples, but containing repeatedly arc-welded and unstress-relieved shoulder pads at the ends of the gage length, was found totally free of graphite after 7002 hr at 950F under 10,000 psi which is $1^1/_4$ times the permissible working stress.

Case 5. A creep-test specimen made of straight silicon-killed McQuaid-Ehn normal- and coarse-grained carbon-molybdenum steel (grain size Nos. 2-4) in the 1650 F annealed (slow-furnace-cooled) condition and containing a standard multiple-pass arc weld, stress-relieved at 1200 F, in the center of the gage length, was found free of graphite after 5800 hr at 1000 F under 10,000 psi which is twice the working stress permitted by the Boiler Code.

Case 6. An identical creep-test specimen as just described, but with an unstress-relieved weld in the center of the gage length, was found to contain scattered medium-sized graphite nodules in both the weld-affected and weld-unaffected metal after 13,420 hr at 1000 F under 10,000 psi, which again is twice the allowable working stress, Fig. 22 (*a* and *b*).

Case 7. Another creep-test specimen of the same annealed straight silicon-killed carbon-molybdenum steel as previously described (cases 5 and 6) and again containing a 1200 F stress-relieved standard multiple-pass arc weld in the center of the gage length, also displayed scattered medium-sized graphite nodules in both the weld-affected and weld-unaffected metal after 13,440 hr at 1000 F under 10,000 psi. Number and size of the graphite nodules were not markedly different from those in the unstress-relieved weld specimen of case 6, Fig. 23 (*a* and *b*).

Case 8. An unwelded section of a refinery tube of straight silicon-killed McQuaid-Ehn normal and coarse-grained carbon-molybdenum steel was found free of graphite after 39,420 hr service at 1050 F under 2140 psi. The steel of this tube contained also 0.61 per cent nickel.

Case 9. Another straight silicon-killed carbon-molybdenum steel refinery tube, containing 0.45 per cent nickel, likewise was found free of graphite after 30,660 hr of service at 1050 F to 1070 F under 2080 psi.

Case 10. A third, straight silicon-killed, carbon-molybdenum

FIG. 23 CREEP-TEST SPECIMEN CASE 7

steel refinery tube with 0.48 per cent nickel also was found free of graphite after 30,660 hr of service at temperatures of 1080 to 1100 F under 1860 psi.

These examples permit some interesting deductions. A study of cases 1 and 3 shows that susceptibility to graphitization is not a direct function of the amount of aluminum added in deoxidization practice and that two steels may possess similar McQuaid-Ehn case characteristics and yet display a marked difference in susceptibility to graphitization.

A comparison of cases 2 and 3 demonstrates that weld-affected metal in the stress-relieved condition is decidedly more susceptible to graphitization than normalized and stress-relieved metal.

Cases 5 to 7 show that straight silicon-killed McQuaid-Ehn coarse-grained and normal carbon-molybdenum steel is fundamentally unstable and will graphitize under extreme conditions.

The absence of graphite in the three nickel-containing refinery tubes raises the question whether the resistance to graphitization of these tubes is due to the nickel in the steel. The authors have expressed the opinion that nickel, dissolved in the ferrite, may prevent graphitization by interfering with the carbon diffusion due to distortion of the ferrite lattice and by forcing more molyb-

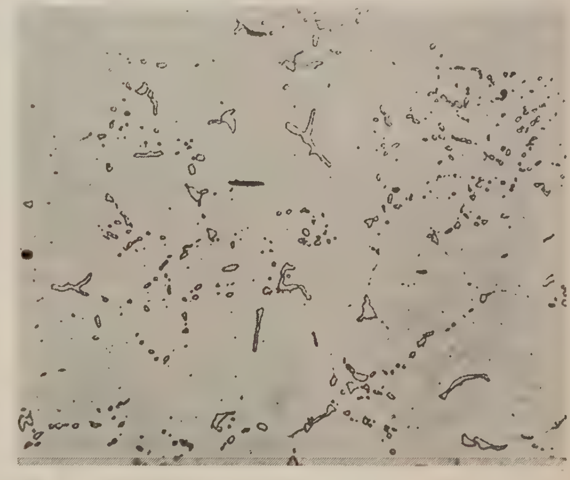

FIG. 24 MICROSTRUCTURE OF REFINERY-TUBE, CASE 9; ×500

denum into the carbide. The microstructure of the three refinery tubes, an example of which is depicted in Fig. 24 of this discussion, shows a high degree of carbide diffusion, spheroidization, and coalescence. One can readily imagine that a low rate of carbon diffusion may retard the beginning of graphite formation and the growth of the graphite cells formed, but in the case of a steel which has undergone fargoing carbide diffusion and coalescence, the rate of carbon diffusion does not seem to have been a factor in preventing graphitization. It also appears to us to be doubtful that nickel conferred stability to the ferrite against carbon rejection in the form of graphite by mechanically strengthening the ferrite, i.e., by increasing the work to be done by the volume expansion resulting from the carbide dissociation, since another element, silicon, which is a much more powerful ferrite strengthener than nickel, is known to promote carbide dissociation. However, the possibility that nickel dissolved in the ferrite forces more molybdenum into the carbide, as suggested by the authors, remains.

One may also wonder if the addition of an element which dissolves in the ferrite, such as nickel, does not modify the electrostatic balance in the ferrite lattice in a manner which is less favorable to carbon rejection in the form of graphite. It all goes to show that there is much to be learned yet before a full understanding of the phenomenon of graphitization is attained. The authors have presented some significant facts and have indicated a new approach to the solution of this difficult problem for which they deserve appreciation and thanks.

L. H. Carr.[6] In the Edward laboratories, we have been making extensive graphitization tests for the past year and a half. We have obtained a certain amount of test data which does not differ in its essential details from most of that which has been presented already. The tests show up many of the same anomalies which have already been pointed out. They seem to show that we all know a number of factors which definitely have to do with a tendency toward graphitization, but that we do not know for sure of an economical solution which can be applied to steelmakers the country over which will guarantee the absence of graphite for service times of 5 to 25 years.

For example, we have found such conflicting data as the following: Samples of cast carbon-molybdenum steel from one foundry source deoxidized with 2 lb of aluminum per ton will develop graphite in every test. Samples of the same material again deoxidized with 2 lb of aluminum per ton from another foundry source have never developed graphite in any of our tests. On the other hand, the foundry source whose material graphitizes with high aluminum addition, has made a number of test bar heats of either no aluminum or $^1/_2$ lb per ton. None of these specimens has graphitized in our tests, but other investigators have found graphite developing in steels of low aluminum additions. We have tested a good many heats of steel graphitized when stress-relieved at 1200 F after welding, and none of them showed graphite when stress-relieved at 1300 F after welding. Again, however, other investigators have reported this as not being a foolproof preventive. We have tested a number of heats of cast carbon-molybdenum steel containing from 0.40 to 0.60 per cent chromium for test periods as long as 10,000 hr at 1025 F. Again none of these specimens has shown graphite, although we have heard from other investigators that they have found graphite in some steels containing chromium.

Again, we might call attention to a number of pipe investigations wherein graphite has been found distributed in a number of random locations away from any apparent welding or heating. It would seem therefore that perhaps graphitization is a little bit like creep in that at high temperatures we will always have some, and that the engineering and metallurgical problem is to minimize this tendency toward graphitization, rather than to try to erase it 100 per cent in all cases.

In view of the fact that different steelmakers, using nominally the same practice, produce carbon-molybdenum steels of widely differing graphitization tendencies, it would seem that too much weight could not be given to the results of any one graphitization investigator. Furthermore, it is felt that too many suggested solutions to the whole problem have been discarded because of just one or two graphite spots widely distributed in a sample. Since no simple cure-all for the matter has been developed, it would seem that the best way to give engineers the information they need today would be to summarize all available test information in some sort of a statistical score sheet. This might show, for example, that of several thousand specimens of high-aluminum carbon-molybdenum steel 30 per cent would show graphitization at the end of a certain testing time. It might show in the case of several thousand other low-aluminum carbon-molybdenum steels that 3 or 4 per cent would show graphitization under similar time and temperatures. Again, it might show that of specimens stress-relieved at 1300 F, a certain per cent would show graphitization. Several hundred specimens of chromium containing carbon-molybdenum steels might show that only one or two had developed any graphite. It would also be desirable to work out some simple method of classifying the degree of graphitization. A simple statement of "Yes, it is present," or "No, it is not," leads to the condemnation of many test samples which are structurally quite sound, but which show one or two isolated graphite spots. Samples in which two out of three fields of view show no graphite in the critical area should perhaps receive a separate classification.

It is believed that a large amount of data of this sort is now available in laboratories throughout the country, which will represent the widest possible range of steel manufacture. A table of this sort should enable engineers to select materials for today's problems on a much more rational basis than merely listening to the opinions of any one or two investigators.

Authors' Closure

The authors are indebted to Mr. Eberle and Mr. Carr for their discussions and interest. The cases cited by Mr. Eberle are significant in illustrating the profound influence of minor variations of treatment on graphitizing tendency. In our own work we have found that in certain samples which were presumed to be homogeneous, since they were cut out of larger parts which had been treated as a whole, a particular region would display a marked shower of graphite particles while the remainder of the sample would be devoid of visible graphite (on the same polished section). This made for great tedium in the microscopic examination for the failure to find graphite at the first examination gave no assurance graphite was not present and in significant quantity. Particular conditions of divorcement of ferrite and carbide were suspect, as brought out in the paper and if graphite was not found in the first instance, the sample was ground down and repolished through successive layers until there was reasonable assurance that graphite either was or was not present.

This critical examination was required by the nature of the Springdale failure and by the findings on the graphitized valve body described in the paper. The graphite found on a particular section may not be significant in revealing the degradation of the whole member. This was brought out by Blumberg in the general discussion of graphitization at the December, 1943, meeting of the A.S.M.E.

The foregoing comments will partially serve in reply also to Mr. Carr. The compilation and statistical analysis of graphitiza-

[6] Director Research, Edward Valves, Inc., East Chicago, Ill. Mem. A.S.M.E.

tion data suggested by Mr. Carr would possess a certain interest but would afford small satisfaction to the design engineer. To lay out a power plant with the knowledge that 30 per cent or even 3 per cent of the steels involved would graphitize within the normal service life, perhaps seriously, would not be very comforting. It is quite true that we shall always have a little creep at these high temperatures but creep is something that can be measured and predicted and loading values are selected so that total creep over service expectancy is kept small in amount. However, the action through which controlled creep takes place does not lead to marked degradation of the physical properties. Graphitization involves degradation and may in some instances lead to serious failure. We therefore believe that erasing of graphitization 100 per cent *is* the metallurgical problem and to fail to strive for that end is not sound.

Question has been raised regarding usage of 1100 F as a graphitization test temperature. The results presented at this session of the Joint E.E.I.-A.E.I.C. Investigation supports our position in this. Although we made no detailed attempt to measure graphitization quantitatively, qualitatively it appeared from our results that time was the principal factor affected by using higher temperatures. Furthermore, 1100 F is a directly significant temperature when it is considered that in some newer installations operating swings will closely approach it.

We affirm our position that for increasing the relative stability the judicious use of alloys offers the safest approach. Also, the mechanisms are such that simple concepts, for example that thermodynamic stability of carbides is the only factor, may be not only misleading, but also dangerous. In support of our findings on WC-4 steel other investigators working within the chemistry of this specification have found samples with weld metal deposited thereon resistant to graphitization in the weld-affected zone over periods up to 10,000 hours at 1100 F. If the chart on graphitization rates prepared for the Summary Report of the Joint E.E.I.-A.E.I.C. may be presumed correct this would be the equivalent of 100,000 hours at 925 F.

Influence of Heat-Treatment Upon the Susceptibility to Graphitization of High-Aluminum-Deoxidized Carbon-Molybdenum Steel

By F. EBERLE,[1] BARBERTON, OHIO

Susceptibility to graphitization of carbon-molybdenum steels may be influenced by heat-treatment of the material prior to installation. Tests are reported in this paper on high-aluminum-deoxidized pipe with welded upset ends, the upsetting being carried out at 2000 F without subsequent heat-treatment. Graphitization in certain zones of the pipe were in evidence. Subsequently the influence of prior heat-treatment or weld heat effects upon susceptibility to graphitization was explored. The procedure and results attained are recorded in this paper.

Introduction

A STUDY of the behavior of carbon-molybdenum steels in long-time service at steam-plant operating temperatures led to the observation that susceptibility to graphitization may be influenced by the heat-treatment of the material prior to installation. For example, in high-aluminum-deoxidized pipe with welded upset ends, the upsetting being carried out at 2000 F without subsequent heat-treatment, the following conditions might be encountered:

(*a*) High-temperature end of weld-affected upset material: not graphitized.

(*b*) Low-temperature (1300–1400 F) zone of weld-affected upset material: graphitized.

(*c*) Weld-unaffected upset part of pipe: not graphitized.

(*d*) Transition zone from the upset to the unupset part of the pipe which had been heated to and cooled from a temperature of 1300–1400 F: graphitized.

(*e*) Heat-unaffected unupset body of the pipe: graphitized or not graphitized, depending on the heat-treating temperature and rate of cooling prior to installation.

This influence of prior heat-treatment or weld heat effects upon susceptibility to graphitization was subsequently explored with a series of experiments designed to examine the following factors:

1 Rapid cooling from very high temperatures as sometimes encountered in upset pipe ends and in the high-temperature zone of weld-affected metal.

2 Slow cooling from very high temperatures, sometimes found in pipes and heavy castings.

3 Rapid cooling from temperatures above but in the vicinity of the A_3 point of the steel as employed in standard normalizing treatment.

4 Slow-cooling from temperatures above but in the vicinity of the A_3 point of the steel as met in "normalized" heavy castings.

5 Rapid and slow cooling from temperatures just above the A_1 point of the steel after heat-treatments (1) to (4) as may occur in the low-temperature zone of weld-affected metal ("contact zone").

6 Quenching of normalized material from temperatures just above and just below the A_1 point of the steel as may be encountered in the contact zone between weld-affected and weld-unaffected metal.

7 Annealing at 1200 F and 1300 F, respectively, as employed for stress-relieving.

No attempt was made in these experiments to reproduce exact fabrication conditions, i.e., the rate of cooling in the normalized samples was sometimes faster, the quenching of the quenched samples more drastic, and the cooling of the annealed samples slower than in fabricated material. This was done purposely in order to establish fundamental trends and, if possible, to shed more light on the mechanism of graphitization.

Experimental Procedures

For some of the tests only unwelded specimens were used, consisting of $^3/_4$-in. cubes machined from the heat-treated material so as to eliminate oxidized and decarburized surface metal. In general, the heat-treating was done in a salt or lead bath. Some tests with unwelded material were run in duplicate, one set of specimens remaining in the heat-treated and machined condition, while identical specimens of a second set were 50 per cent cold-compressed in a tensile machine prior to the soaking in the lead bath at 1000 F. This severe cold deformation had been found generally to promote or accelerate graphitization and helped to induce the formation of graphite in some conditions of heat-treatment where it would otherwise not occur, at least not within the chosen duration of the tests.

A second set of experiments was conducted with special spot welds consisting of 1-in-diam × $^1/_8$-in-thick disks which were prepared by placing them between the water-cooled electrode tips of a spot-welding machine and applying sufficient current to fuse the core of the disks from cold to fusion within $^1/_{15}$ sec, $^2/_{15}$ sec, and $^1/_5$ sec, respectively, the disks then cooling to room temperature within 1 sec. These tests were intended to give information on the effect of extremely rapid cooling under conditions of welding.

A third series of tests was carried out with regular multiple-pass arc welds prepared by joining two plates which had been water-, air-, or slow furnace-cooled from 2200 F and 1650 F, respectively, prior to the welding, water-cooled plate being welded to water-cooled plate, and air-cooled plate to air-cooled plate, etc. Each

of these test welds was then cut into three sections, one section remaining in the as-welded condition, a second section being standard stress-relieved at 1200 F and the third section annealed at 1300 F for 20 hr. These tests were intended to furnish information on the effect of various heat-treatments under actual fabricating conditions.

All graphitization tests were conducted in a charcoal-covered lead bath held at 1000 F.

Materials

Two types of carbon-molybdenum steel were employed: Two high-aluminum deoxidized steels of great susceptibility to graphitization (steels A and B) and a high-aluminum-deoxidized steel of low susceptibility to graphitization (steel C). The deoxidation practice, McQuaid-Ehn case characteristics, and chemistry of these steels are given in Tables 1 to 6 which also contain summaries of the test results.

TABLE 1 TEST SERIES A—TESTS WITH UNWELDED SPECIMENS IN VARIOUS CONDITIONS OF HEAT-TREATMENT

Test Results

Evaluation of the test results led to the following conclusions:

1 Carbon-molybdenum steels deoxidized with the same nominal amount of aluminum, possessing practically identical chemistry and displaying practically identical abnormal McQuaid-Ehn case characteristics may show differences in susceptibility to or rate of graphitization.

2 Annealing at very high temperatures followed by rapid cooling seems to inhibit or retard graphitization at the contemplated temperatures. This was found to be true also for specimens which had been 50 per cent cold-reduced by compression prior to the subcritical annealing at 1000 F.

3 Annealing at temperatures above, but near the A_3 point of the steel followed by rapid cooling appears to be much less effective in retarding graphitization than rapid cooling from very high temperatures. When severely cold-deformed, such material may form graphite within 1500 to 3000 hours at 1000 F.

4 Annealing at very high temperatures followed by slow cooling seems to promote or accelerate graphitization. In this condition relatively large scattered graphite nodules are formed within 1500 hours at 1000 F.

5 Annealing at temperatures above, but near the A_3 point followed by slow cooling renders the steel less susceptible to graphitization than slow cooling from very high temperatures, but more susceptible than air cooling from temperatures above but near the A_3 point.

6 Reheating steel which had been rapidly cooled from very high temperatures and thereby made insensitive to graphitization, to temperatures just above the A_1 point renders it again susceptible, irrespective of the subsequent rate of cooling.

7 Heating to just above the A_1 point (1400 F) followed by water-quenching renders the steel more susceptible to graphitization than slow furnace-cooling from the same temperature. On the other hand, slow-cooling from just above the A_1 point favors graphitization more than air-cooling. In this connection it should be remembered that quenching from very high temperatures inhibited the formation of graphite more effectively than any other heat-treatment. The high susceptibility to graphitization resulting from quenching from just above the A_1 point therefore deserves particular attention.

8 Steel which previously had been heated to very high temperatures appears to be rendered slightly more susceptible to graphitization when subsequently reheated to just above the A_1 point than steel which previously had been heated to temperatures above but in the vicinity of the A_3 point.

9 Material which had been slow furnace-cooled from temperatures above the A_3 point appears to be slightly more susceptible to graphitization when subsequently reheated to temperatures just above the A_1 point than previously fast-cooled material. Steel slowly cooled from very high temperatures, reheated to above the A_1 point and then severely strained, shows a tendency to form continuous grain-boundary chain graphite.

10 Quenching from temperatures just above the A_1 point seems to favor graphitization more than quenching from temperatures just below the A_1 point.

11 Annealing at 1200 F as used in conventional stress-relieving appears to have little effect upon the formation of graphite unless accompanied by a reduction or elimination of stresses. Under like conditions, annealing at 1300 F for the same length of time seems to reduce the number of graphite nodules, but does not seem to prevent their formation.

12 Long-time annealing at 1300 F considerably retards the formation of graphite and also tends to reduce the number of nodules formed.

General Deductions

The pattern of susceptibility to graphitization obtained with the various heat-treatments preceding the isothermal graphitization tests at 1000 F clearly indicates the involvement of a submicroscopic precipitation phenomenon as suggested by Austin and Fetzer.[2] There seems to be a substance, elements or compounds, which upon precipitation in a certain state promote carbide instability. The solution temperature of this substance seems to be rather high and its precipitation from solution relatively sluggish. Air-cooling from temperatures above 2000 F appears to suffice to retain these elements or compounds in solution even in the extremely sensitive high-aluminum-deoxidized steels and in this condition the steel will not graphitize within 10,000 hr at 1000 F, as demonstrated by the behavior of the spot-weld-fused samples. Heating the steel to intermediate temperatures above but in the vicinity of the A_3 point apparently does not create complete solution, and diffusion of the submicroscopic phase and abnormal steel air-cooled from such temperatures will therefore graphitize under favorable conditions, as for instance, when severely cold deformed. Slow cooling from very high and from intermediate temperatures precipitates the phase and renders the steel susceptible to graphitization. Complete solution and diffusion of the phase as obtained at very high temperatures seems to result in a more effective state of precipitation than incomplete solution and diffusion as obtained at intermediate temperatures.

If steel which had been rapidly cooled from high temperatures is subsequently reheated to temperatures just above the A_1 point, the dissolved phase will at least partly precipitate and render the steel again susceptible to graphitization. It is suspected that the allotropic transformation at the A_1 point, particularly when combined with straining, aids the precipitation of the submicroscopic phase. The preferential occurrence of graphite in the low-temperature zone of weld-affected metal may be similarly explained. Short-time annealing at 1200 F and 1300 F apparently

[2] "Factors Controlling Graphitization of Carbon Steels at Subcritical Temperatures," by C. R. Austin and M. C. Fetzer. Trans. A.S.M., vol. 39, 1945, pp. 485–535.

fails to bring about effective precipitation of the phase. On the other hand, once the phase is precipitated, annealing at 1200 F and 1300 F tends to render the phase ineffective, presumably by coalescence or agglomeration. At 1200 F, this effect seems to be very slight and even at 1300 F a relatively long annealing time is required to produce results of practical significance.

Practical Conclusions

Applying the foregoing deductions to the practical aspect of graphitization in welded structures, the following conclusions suggest themselves:

1 Normalized material is slightly less susceptible to graphitization than annealed material.

2 Normalizing at temperatures close to the A_3 point offers a better safeguard against the formation of dangerous chain graphite than normalizing at very high temperatures.

3 Welding conditions should be chosen so as to minimize strain in the weld-affected metal by suitable preheating.

4 Long-time stress relieving at 1300 F is more advantageous as a safeguard against graphitization than conventional stress-relieving at 1200 F.

General Discussion of Graphitization Papers

S. H. WEAVER.[1] The General Electric graphite furnace heats bars with a lengthwise weld bead to 900 F at one end and 1300 F at the other end. All bars were notched at the 1100 F location for examination after 3000 hr. The 6200-hr study has been partially completed.

Fig. 1 of this note, for items 1 to 7, Table 1, gives the graphitic growth by chemical analysis in 3000 hr for different temperatures upon 0.15 per cent carbon steel with different deoxidization. The 1200 to 1300 F points were omitted because of decarburization of the steel. The furnace was then changed to dry nitrogen atmosphere.

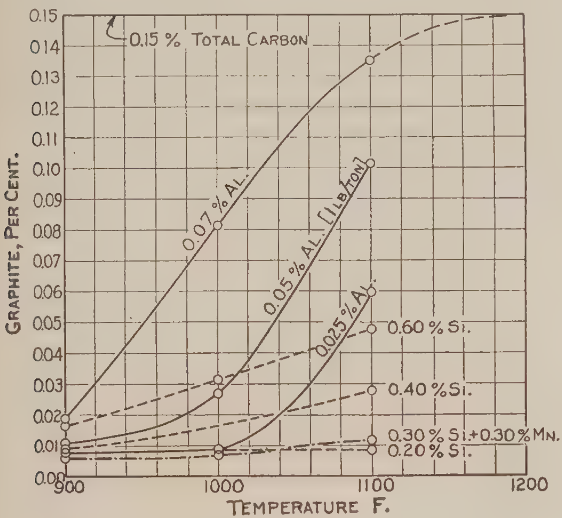

FIG. 1 GROWTH OF GRAPHITE AT 3000 HR IN 0.15 PER CENT CARBON STEEL

In the alloy series in Table 2 of this note, items 8 to 16 have no microscopic graphite after 6200 hr at 1100 F.

Table 3 lists nine conditions of pipe to A158-36P1 with 2 lb per ton of aluminum where at 1100 F in 3000 and 6200 hr all contained small nodular graphite except the 2300 F upset-end sample.

The four items of pipe in Table 4 to A206-42T with 1 lb per ton of aluminum, and the four items in Table 5, with 0.4 lb per ton of aluminum have shown no graphite at 1100 F. No examination has been made at other temperatures.

There are 19 other bars in the furnace including samples of 1 per cent Mo; 1 per cent Mo, 0.2 per cent V; 0.5 per cent Cr, 0.5 per cent Mo, in each case with varying practices as regards heat-treatment and deoxidization practice. No graphite has been observed after the first 1700 hr. A longer soak will be required before any conclusion can be drawn from these latter test bars.

Some Stress-Corrosion Studies on Austenitic Cast Irons

By J. B. Urban,[1] J. W. Bolton,[1] and A. J. Smith[1]

Experimentation is the most adequate approach to stress-corrosion problems and should involve various mechanical loadings of a material under corrosive conditions. When corrosive conditions are held constant in respect to concentration and temperature, useful threshold stresses if existent can be ascertained and suitable safety factors adopted. The procedure for studying austenitic cast irons on this basis is discussed, the investigation indicating that at very high stresses, such irons are subject to stress corrosion in strong hot caustic. However, threshold stresses have been found to be relatively high, markedly exceeding stresses contemplated in design and application. Thus the desirable properties of such material can be utilized to good advantage, with margin to assure adequate safety in this corrosive medium.

Problems of stress corrosion have concerned engineers for many years. "Season-cracking" in brasses and embrittlement of ductile boiler-plate steel in presence of alkaline media are familiar examples. A material may possess apparently adequate strength and adequate corrosion resistance, as ascertained by separate conventional tests. Yet some materials are known to fail prematurely when exposed to certain combinations of these factors.

It is known that triaxiality of stresses may bring about acceleration of failure, or failure at lower loading than would be expected from conventional formulas for mono- and biaxial loading. Somewhat similarly, "corrosive stress" may be considered as an additional stress imposed upon a normally loaded system, giving the effect of higher stress order than contemplated by formulas. The safest approach to stress-corrosion problems is experimentation on various mechanical loadings under corrosive conditions. When corrosive conditions are held constant in respect to concentration and temperature, useful threshold stresses if existent can be ascertained and suitable safety factors adopted.

Since stress corrosion is initiated as a surface effect, it is essential that surface stress intensities (as imposed by loading) be determined accurately, so that the result of imposition of a corrosive condition can be evaluated. The resistance-wire (SR-4) type strain gage has proved quite useful in this respect.

Strong hot caustic (sodium hydroxide) is a powerful corrosive toward many metals, and produces embrittlement in some. Suitable grades of gray cast iron have fairly good resistance toward the corrosive effect and also are relatively free from stress-corrosion deterioration. Some of the high-nickel austenitic cast irons have excellent corrosion resistance toward strong caustics, even at elevated temperatures. This suggests their consideration[2] where contamination of caustic must be held to a minimum and where maximum life under such corrosive conditions is desired.

The present investigation indicates that at very high stresses the austenitic cast irons are subject to stress corrosion in strong hot caustic. However, threshold stresses have been found to be relatively high, markedly exceeding stresses contemplated in design and application. Thus the desirable properties of such material can be utilized to good advantage, with margin to assure adequate safety in this corrosive medium.

Experimental Procedures

Compositions of the materials examined are given in Table 1. Samples of austenitic-type cast iron were immersed in 50 per cent caustic solutions and boiled, using reflux condenser, for periods up to 6 months. These were broken in impact test. The test results were equal to those of companion samples not exposed to caustic. This showed that caustic embrittlement does not result when stress is absent.

TABLE 1 COMPOSITION OF MATERIALS

Molybdenum	0.74	0.90	0.63	0.62	...
Copper	4.10	0.06	4.55	4.33	...

Other samples were loaded under standard creep-test conditions.[3] These tests showed that the materials involved withstand stresses to 15,000 psi at 350 F, without measurable flow or "creep." After removal from the creep test and breaking, no differences in strength and ductility from companion unstressed samples were observed. These and other tests indicate that even at relatively high stresses the material is not adversely affected by mechanical loadings, even at temperatures appreciably above 350 F. The question then is whether the combined actions of stress and exposure to the corrosive medium produce effects not indicated by these factors operating independently.

The corrosive medium and condition chosen was 50 per cent by weight commercial sodium hydroxide (aqueous solution) at 280 F.

Three methods of stress application utilized were as follows:

Note: Statements and opinions advanced in papers are to be understood as individual expressions of their authors, and not those of the Society.

[2] Austenitic cast irons also are resistant to many other corrosive agents, both alkaline and acid, wherein long experience has shown that stress corrosion is not a factor.

[3] "Recommended Practice for Conducting Long-Time High-Temperature Tension Tests of Metallic Materials," A.S.T.M. Standards, 1941, E22-41.

(*a*) tensile loading, (*b*) cantilever loading, and (*c*) beam loading.

All specimens were cast in green sand and tested in the unmachined condition. (This simulates the surface conditions of cast product as commonly used.)

Tensile Loading Method

The arrangement of equipment is shown in Fig. 1. The test specimen was mounted between high-nickel-alloy pulling bars supported at the top with a ball-and-socket joint and a dead load applied to the bottom. The bottom bar passed through the base of a high-nickel-alloy container with a watertight seal, the container being filled with solution of commercial sodium hydroxide. A heating element around the container maintained the desired temperature of 280 F, through a potentiometer controller and thermocouple. (This temperature is very near the boiling point.) Water lost through evaporation was replaced continuously through a simple gravity-feed mechanism holding the solution concentration relatively constant. The average stress intensity over the affected area was established by the sum of the weights of container and contents, lower pulling bar, and applied weights.

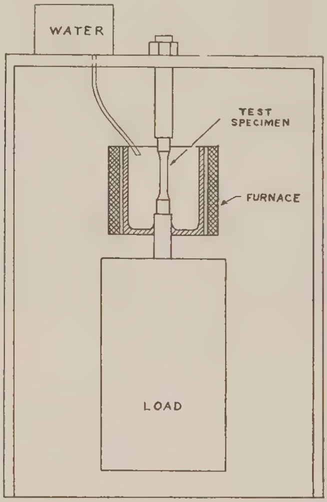

Fig. 1 Stress-Corrosion Test Setup for Tensile Loading

Simple- and Cantilever-Beam Loading Methods

These systems are shown in Figs. 2 and 3. The ends of the test specimens were attached to the load through a wire passing over a ball-bearing-mounted pulley of low frictional resistance. By means of this arrangement stresses on the specimens were independant of flexural changes in the supports, within reasonable limits of flexure of specimens.

Tests were carried out both on round specimens 0.5 in. diam, and specimens of rectangular cross section measuring 1 × 0.4 in. Specimens were $8^1/_2$ in. in length in the cantilever test; in the simple-beam tests the outer knife-edges were $9^1/_2$ in. apart, the center knife-edge $3^1/_2$ in. from the lower fixed edge.

In conventional engineering practice stress intensities (as rupture moduli) usually are calculated by the beam formulas. These formulas are based upon the assumptions of elasticity and equivalent stress-strain moduli in both tension and compression. Cast irons do not comply with these assumptions. As shown by the authors' company[4] and others, the stress-strain curve of cast irons combines both elastic and plastic components. Also, properties are not equivalent in tension and compression. Thus the neutral stress axis does not coincide with the geometric axis.

[a] Not broken.

Since stress-corrosion phenomena are (at least at their incidence) influenced by surface conditions, accurate measurement of fiber stress is necessary for evaluation. Strain-resistance (SR-4) gages are quite useful for this purpose. SR-4 gages and instrumentation have been described in detail in recent literature. Many applications have been to elastic materials. In such applications the measured strain is interpreted in terms of stress by introduction of Young's modulus.

Since the materials studied are but quasi-elastic, a modified procedure was required. Relationship of strain to stress not being constant, strain readings must be compared to a separately determined stress-strain curve to ascertain the corresponding stress intensities. The details of procedure and the various calibrations are described in the Appendix. The SR-4 strain-measurements'

[4] "Some Notes on Mechanism of Deformations in Grey Iron," by J. W. Bolton, Proceedingsof the A.S.T.M., vol. 32, part 2, 1932, p. 477.

accuracy compared very favorably with measurements by other extensometric devices and results were readily reproducible. The facility with which these gages can be applied to locations and shapes where strains are not measurable by other devices extends the field of testing engineering. SR-4 gages can be used not only on simple test shapes but also on products and other complicated shapes subjected to stress and strain.

Test Results

Tensile Tests. These are summarized in Table 2 and are shown graphically in Fig. 3. The gray cast iron sustained a tensile load of 25,000 psi for 284 hr and 10,000 psi for 2600 hr without breaking. The solution discolored and the bars showed evidence of surface corrosion but there was no evidence of corrosion being accelerated by the stress, or suggestion that embrittlement was effected.

Austenitic iron failed in a comparatively short time under a load of 20,000 psi, 0.7 hr on one bar, 7.7 hr on another, both from the same heat. Decrease of stress to 12,000 psi increased the time to fracture by almost 3 times. At a stress of 10,000 psi load was sustained for 2600 hr without fracture. The curves indicate that there is a limiting stress below which failure will not occur in caustic solutions. (This is confirmed by long-time service experience with the condition and material.) Above the limiting stress very slight increases in stress profoundly shorten the time to failure. This indicates the desirability of suitable choice of design stress, and measurements under operational conditions to reveal it.

The tensile strength of iron A, cast as a 0.5-in-diam specimen was 38,500 psi. The specimen removed unbroken after 270 hr in hot caustic under a stress of 11,000 psi was subsequently broken at room temperature and showed a tensile strength of 37,900 psi. A piece of the test specimen which failed after 43 hr at 12,000 psi was broken at room temperature, giving a tensile strength of 38,600 psi. It would appear that the caustic is effective only in lowering the time to fracture under stress when material is under the corrosive and temperature influence.

Beam Loadings. Results obtained from beam loadings of specimens are recorded in Table 3, and plotted in Fig. 4. The upper curves show the tensile fiber stress as calculated from the beam formula, the lower from conversion of actual strain measurements according to the method described in the Appendix. The marked error occasioned by use of the beam formula is evident.

These results are in good agreement with those found for tensile loading, the limiting or threshold stress being about 10,000 psi.

Conclusion

These studies show that for the corrosive and temperature considered there is a limiting stress below which the effects of stress corrosion on austenitic irons are either negligible or nonexistent. This stress is relatively high in respect to contemplated stresses for cast-iron products. Thus the good corrosion resistance of these metals in hot caustic can be advantageously utilized as sound engineering practice. This confirms field experience.

As shown by these studies (and described in the Appendix), the SR-4 resistance-strain-gage method is a valuable tool for the metallurgist and test engineer in their evaluation of quasi-elastic materials.

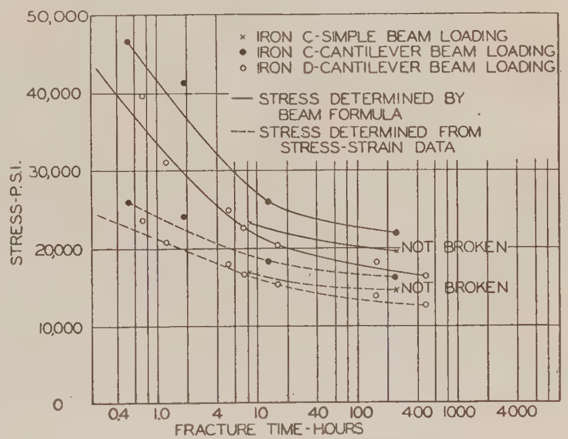

Fig. 4 Stress-Corrosion Rate for Austenitic Cast Irons; Transverse Loading

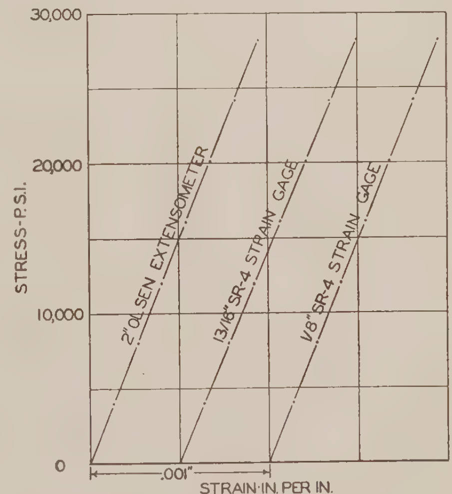

Fig. 5 Comparison of Strain Gages

(Gages mounted on steel tensile-test specimen. Readings were taken simultaneously on all gages.)

Appendix

The foregoing paper indicates the necessity of correct stress evaluation in studies of stress-corrosion effect.

Stresses due to tensile loading are determined readily and directly. Those due to various transverse loadings are not so easily determined. This is especially so in case of quasi-elastic materials, such as cast irons, where the premises of beam formulas do not apply, and strain measurements by conventional extensometric devices are not readily made.

SR-4 resistance-type strain gages were used to determine the

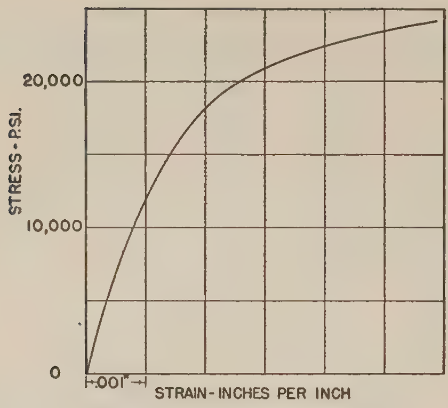

Fig. 6 Tensile Stress-Strain Curve for Austenitic Cast Iron

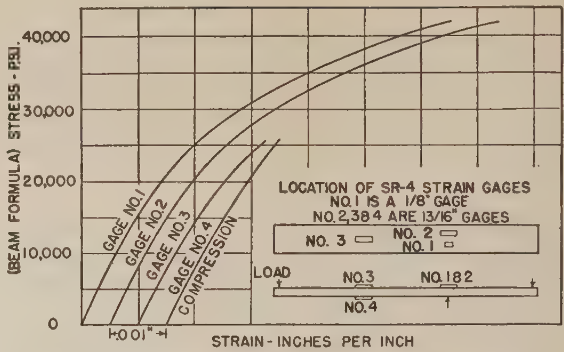

Fig. 7 Stress-Strain Curve on Austenitic Cast Iron
(Simple beam loading.)

strain readings for the transverse loading of the stress-corrosion tests. To check the accuracy and sensitivity of the SR-4 strain gages a steel tensile-test specimen was made long enough to accommodate an Olsen extensometer (2 in. gage length), a $^{13}/_{16}$-in. SR-4 strain gage, and a $^{1}/_{8}$-in. SR-4 strain gage. Simultaneous readings of strains and applied load were taken. The results given in Fig. 5 show good agreement, especially when it is borne in mind that different gage lengths are involved.

A typical tensile stress-strain curve for austenitic cast iron is shown in Fig. 6. Four SR-4 strain gages were mounted on a specimen as shown in Fig. 7, and the specimen was subjected to simple loading in the setup shown in Fig. 2. The applied loads were converted to stress as indicated by the beam formula and plotted against the corresponding strain as shown in Fig. 7. The apparent moduli by beam-formula fiber stress versus strain are considerably higher than those obtained from tensile stress-strain data especially at higher stresses. This emphasizes the fact that stresses determined from beam formulas deviate considerably from the true stresses. The stress-strain data shown in Fig. 7 were obtained on as-cast specimens not subjected to previous stressing. Cast irons are quasi-elastic materials. Therefore stressing will result in plastic deformation and alter the stress-strain characteristics of the material. When strain determinations on a quasi-elastic material are converted to stress, it is imperative that the stress-strain data used in the conversion be obtained on material of similar prior stress history.

Modern Methods in the Heat-Treatment of Steel

By E. R. Mertz,[1] Burbank, Calif.

The construction of time-temperature-transformation curves (S-curves) and their use in developing the interrupted-quench processes for steels are treated in this paper. Of these processes, martempering, austempering, and cyclic annealing are explained in detail. Martempering results in greatly reduced stresses in quenched parts, as compared to the conventional quench and temper method of hardening steel, and hence much less cracking and distortion is apparent. Austempering, an isothermal process producing bainite, develops surprisingly high impact properties in the region of 250,000 psi or 50 Rockwell C. Cyclic annealing is an elevated-temperature isothermal annealing process to produce a predetermined degree of softness, and saves much valuable time in the annealing of the higher alloy steels. The use of hardenability curves in establishing size limitations for particular heats of steel and in selecting accurate tempering temperatures is demonstrated.

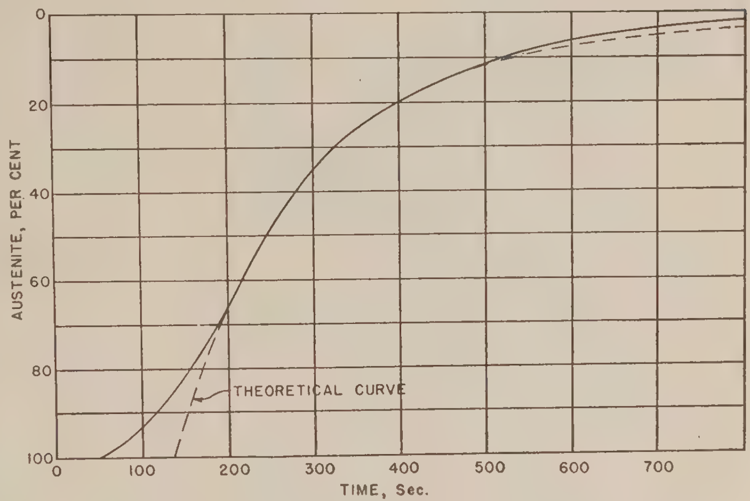

Fig. 1 Reaction Rate of Austenite Compared to Theoretical First-Order Reaction Curve

Introduction

Most of the processes involved in the heat-treatment of steel depend upon the decomposition of austenite into one or more of its transformation products, and the physical properties produced depend upon the nature of the product or products formed. Austenite is a solid solution of carbon in iron which is stable (for most steels) only at elevated temperatures, and when it is cooled below a certain critical temperature the normal solubility of carbon in iron is reduced to a negligible amount. As a result, a reaction occurs which involves a change in the crystallographic structure of the iron, and in most cases the formation of iron carbide and/or other carbides. Bain and Davenport (1)[2] demonstrated that the product formed from the decomposition of austenite was dependent upon the temperature at which the reaction occurred rather than the speed at which the austenite was cooled.

Austenite Decomposition; S-Curves

Fig. 1 illustrates how closely the isothermal transformation of austenite follows a first-order chemical reaction in which the rate of reaction at any instant is proportional to the amount of reacting material remaining. However, there are several notable deviations from a true first-order reaction. Such a reaction begins immediately at a maximum rate and continues at a constantly diminishing rate. Theoretically, it never reaches completion.

Austenite apparently goes through an incubation period before decomposition starts, does not reach its maximum rate until the reaction has progressed an appreciable amount, and does reach completion in a finite time.

Bain and Davenport (1) studied isothermal transformation rates of austenite at various subcritical temperatures and plotted curves of temperature versus time for beginning and end of transformation. The result was the now familiar "S-curve."

Fig. 2 illustrates (2) how these curves were constructed. The progress of transformation at a chosen temperature was followed by quenching numerous thin samples from an austenitizing temperature into a molten metal bath maintained at the chosen temperature. Periodically, specimens were drastically quenched from the constant-temperature bath so that any untransformed austenite would be converted to martensite, the product formed from austenite at low temperatures. Microscopic examination of such specimens properly etched revealed the dark-etching pearlite or bainite in contrast to the lighter-etching martensite.

Thus accurate data on the beginning and virtual end of transformation of austenite to pearlite or bainite were established, but the data on austenite to martensite transformation remained in doubt. Inasmuch as the formation of martensite apparently involves only a space-lattice change, it does not require time for diffusion. Hence many metallurgists were of the opinion that time was not a function of the process, and temperature was the controlling factor.

Fig. 2

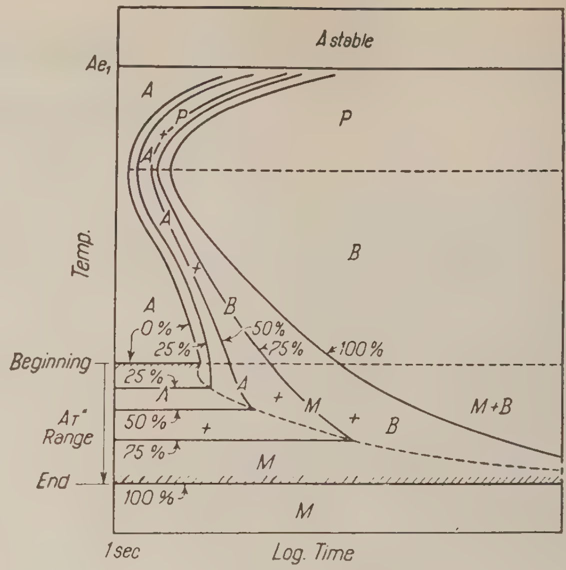

Fig. 3 Modified S-Curve Diagram

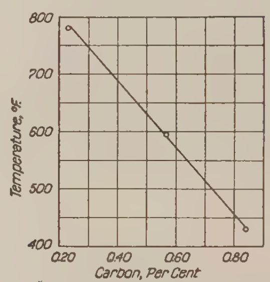

Fig. 4 Effect of Carbon on the M_s of Plain-Carbon Steel

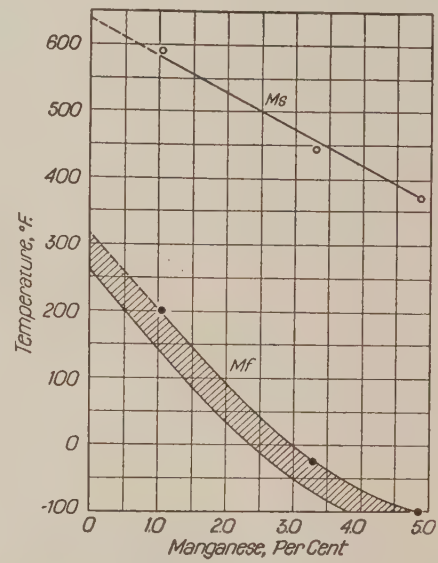

Fig. 5 Effect of Manganese on the M_s and M_f of 0.50 Per Cent Carbon Steel

Martensite Formation; M_s and M_f Points

In a recent investigation Greninger and Troiano (3) were able to follow the progress of austenite to martensite formation by tempering for a short time at a higher temperature the specimens quenched into a low-temperature isothermal bath. The tempering treatment caused any martensite formed to etch darker than freshly quenched martensite, and microscopic examination revealed it in sharp contrast to that formed by quenching after the tempering treatment. The lighter-etching martensite formed by quenching after tempering, represented the untransformed austenite from the original isothermal quench. The results of this investigation established that martensite formation was essentially dependent upon temperature alone. At a given temperature a certain percentage of martensite was formed almost instantaneously and no more was formed unless the temperature was lowered. A constant-temperature product began to appear after a considerable time lag, which amounted to days or weeks at room temperature. This latter product was no doubt a result of diffusion, and was bainitic in structure.

Fig. 3 represents a modified S-curve, or time-temperature-transformation (TTT) curve constructed by Cohen (3), in which the "timeless" nature of martensite formation is incorporated. The dotted line represents the beginning of formation of the isothermal product, which Cohen includes with bainite.

The temperature indicating the beginning of formation of martensite has been designated M_s, and that representing the end, M_f. Fig. 4 is a curve constructed by Greninger (4) showing that the M_s point decreases linearly with increasing carbon content.

Alloys have a similar effect on both the M_s and M_f point, as indicated in Fig. 5 by Payson and Savage (5). They have submitted the following formula for calculating the M_s point, provided, of course, that the austenitizing temperature used is one at which all carbides will be completely in solution in the austenite.

$$M_s \text{ in deg F} = 930 - 570\,C - 60\,Mn - 50\,Cr - 30\,Ni - 20\,Si - 20\,Mo - 20\,W$$

In many steels of high-carbon and high-alloy content the M_f point is well below room temperature, and considerable amounts of austenite are retained by conventional heat-treating procedures. The distortion of accurate gages after long storage may be explained by the eventual transformation of such retained austenite to the isothermal product formed at the storage temperature. Subzero treatment of such steels often transforms much of the retained austenite to martensite, giving a more uniform product, and in many cases a much harder one.

Interrupted-Quench Processes

Complete hardening of a steel part requires the formation of essentially 100 per cent martensite, necessitating a cooling rate at the center fast enough to miss the "nose" of the S-curve where much softer products are formed. Fig. 6 illustrates (6) the conventional quenching process. With rapid quenching the temperature gradient is sufficient to allow the surface of the steel to be almost wholly martensitic while the center is still wholly austenitic. Thus when the center does transform, the expansion due to the austenite-martensite transformation produces tensile stresses in the rigid outer layer of martensite which are often sufficient to produce cracking or at least severe distortion. Such conditions may be minimized by quenching into an isothermal bath above the M_s point and holding at temperature long enough to equalize the temperature throughout the cross section. Air-cooling from this temperature will produce complete hardening, and the thermal gradient will be small enough to allow martensite formation to take place more uniformly from surface to center, minimizing residual stresses. This process is called "martempering," and is illustrated in Fig. 7 (6). The quenching is followed by the usual tempering treatment to produce desired properties.

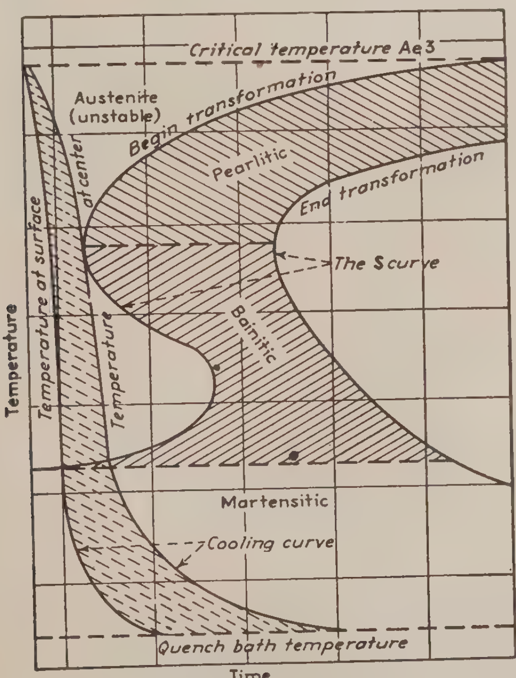

Fig. 6 Cooling Curves in Conventional Quench and Temper Method in Relation to the TTT Curve

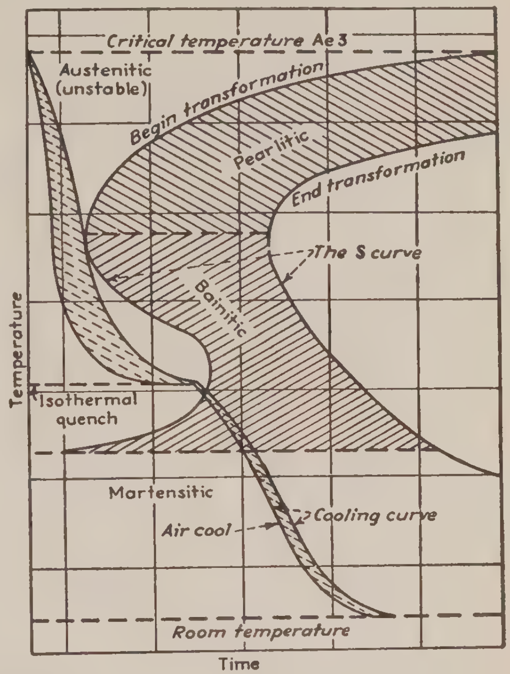

Fig. 7 Cooling Curves in Martempering Method in Relation to the TTT Curve

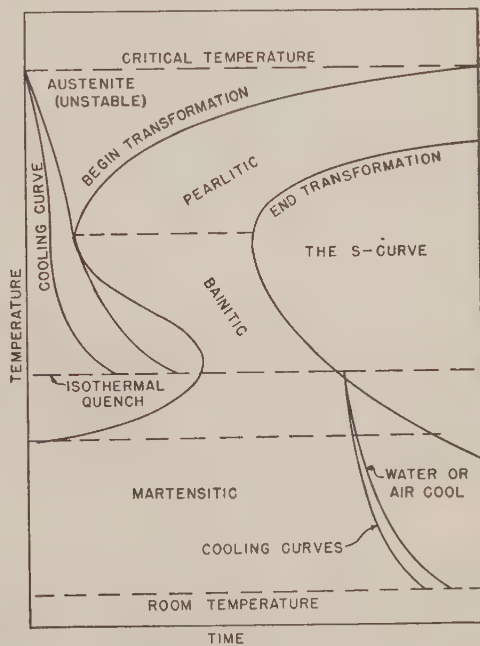

Fig. 8 Cooling Curves in Austempering Method in Relation to the TTT Curve

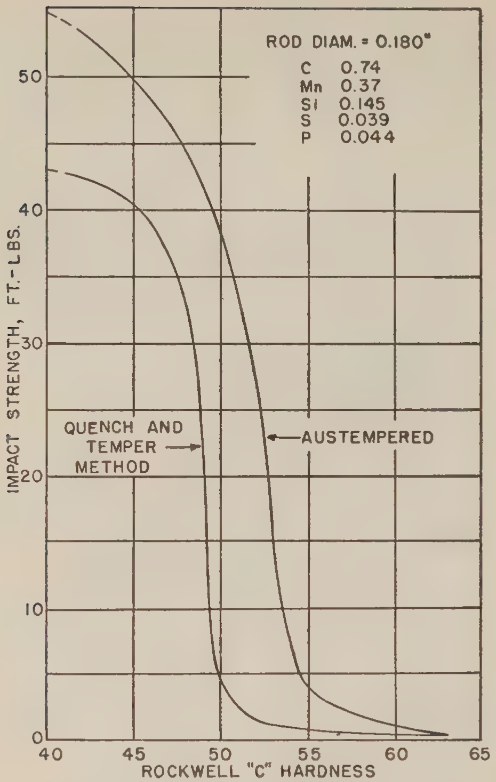

Fig. 9 Comparison of Impact Strengths at Various Hardnesses of Austempered and Quenched-and-Tempered Steels

Fig. 8 illustrates (6) a method of heat-treatment which eliminates the need for tempering. The process, known as "austempering," consists of quenching the steel into a bath held at a temperature where bainite is formed and allowing the austenite to transform isothermally to bainite. The selection of bath temperature determines the hardness of the final product. Steels treated in this manner show considerable improvement in impact resistance, especially in the vicinity of 50 Rockwell C hardness or 250,000 psi, as illustrated in Fig. 9 (7). This process has been applied successfully in the heat-treatment of certain springs, knives, chisels, and other parts where toughness combined with hardness is of importance.

The annealing of steels by furnace-cooling to produce a soft, machinable structure is often a very slow process, especially in the higher-alloy grades which require very slow cooling to avoid some hardening. Much valuable time may be saved by the use of the cyclic annealing process illustrated in Fig. 10 (6). An air furnace operating at constant subcritical temperature may often be substituted for the isothermal quench with little loss of time. The selection of isothermal temperature is dictated by a compromise between time consumption and desired hardness. Higher temperatures produce softer structures, but require longer time.

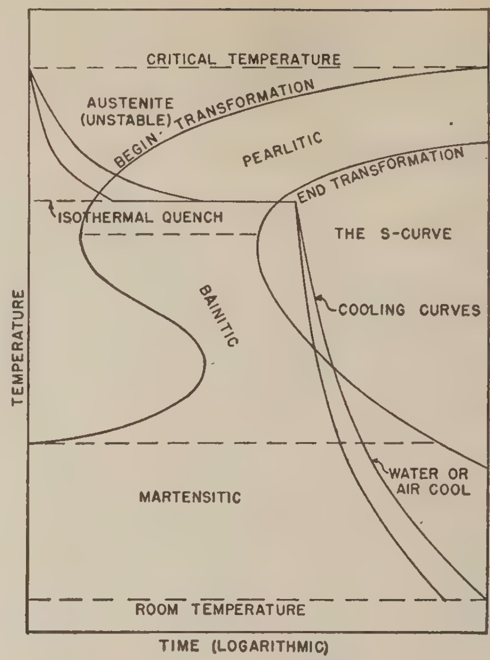

Fig. 10 Cooling Curves in Cyclic Annealing Method in Relation to the TTT Curve

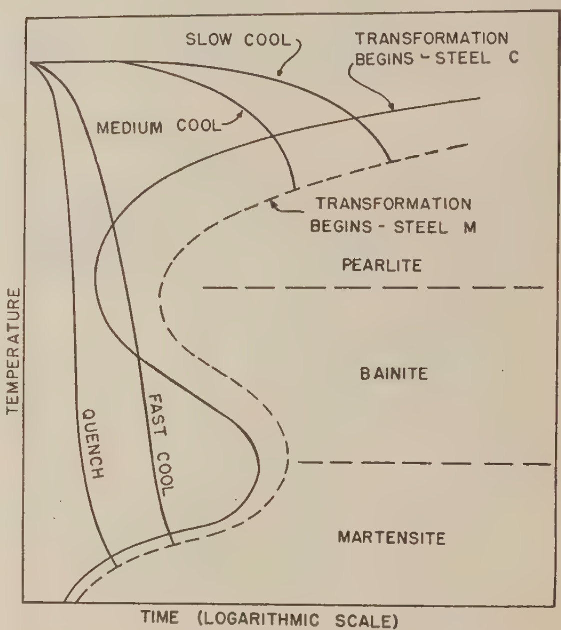

Fig. 11 Comparison of Cooling Rates to Obtain Desired Structures for Two Steels

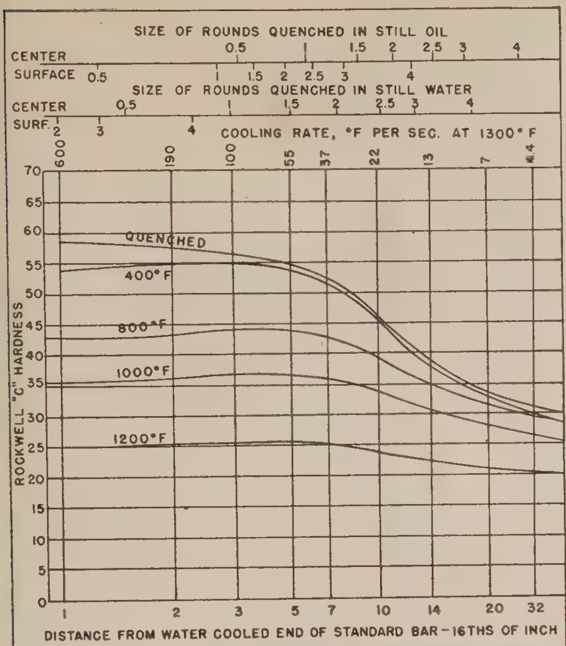
Hardenability

The severity of quench required for complete hardening of a steel depends upon the reaction rate of that steel at the "nose" of the S-curve. If the cooling curve crosses the nose some pearlite and bainite will be formed, and a softer structure obtained. Another steel with more alloy might be completely hardened by the same quench, indicating that its reaction rate at the nose of the S-curve was slower. Fig. 11 illustrates (7) this comparison. The fast cool completely hardens steel M, but incompletely hardens steel C, inasmuch as it crosses the nose of the S-curve. The construction of an S-curve for a given heat of steel is very time-consuming, so other methods of determining the hardenability of steels are used. Most popular is the end-quench hardenability



STEEL	C	Mn	P	S	Si	Ni	Cr	Mo	QUENCHING TEMP.	HT. NO.	GRAIN SIZE

Fig. 13 Standard End-Quench Hardenability Curves for an S.A.E. 1040 Steel

test devised by Walter E. Jominy. This test makes use of the fact that a heated steel bar, quenched only on the end by a jet of cold water, will have a very rapid cooling rate at the point of impingement of the water jet, and a continually decreasing cooling rate at increasing distances from the quenched end. Inasmuch as such cooling rates have been established, a longitudinal hardness traverse of an end-quenched bar will determine what cooling rates are necessary to produce specific hardnesses in the steel from which the bar was made. By correlation of these cooling rates with known cooling rates in fully quenched bars, the hardnesses in such bars may be predicted.

Figs. 12 and 13 show end-quench hardenability curves for two steels. These are supplemented by curves for the same steels tempered at various temperatures.

Correlation of Hardenability Data to Cross-Sectional Hardness Data

Figs. 14 and 15 are correlation charts to be used in conjunction with hardenability curves to convert rapidly end-quench hardness values to cross-sectional hardness values. These charts were constructed by plotting established cooling rates (8) as abscissas against section size as ordinates. Cooling rates are necessarily

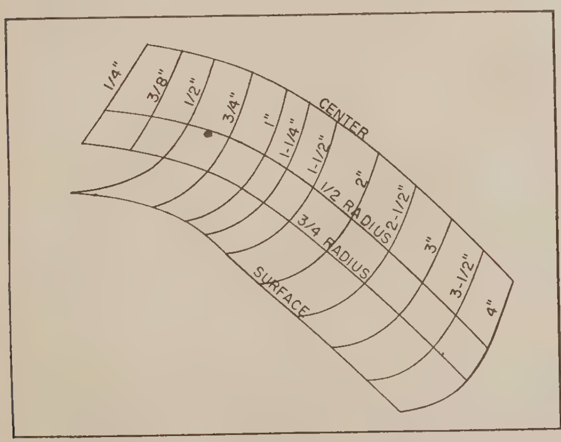

Fig. 14 Correlation Chart; End Quench to Section Hardness; Oil Quench

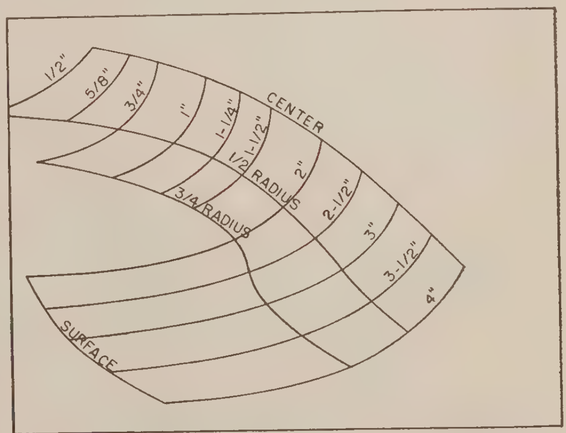

Fig. 15 Correlation Chart; End Quench to Section Hardness; Water Quench

on the same scale as those which appear in Figs. 12 and 13. Construction lines are deleted to avoid confusion. For use, the correlation charts are constructed on transparent paper or copied on photographic film. The use of the water-quench correlation chart is illustrated in Fig. 16. The chart is superimposed on Fig. 13 so that the vertical index line at the left falls on the left border line of Fig. 13. By sliding the chart up or down (keeping the vertical lines indexed) hardness values are read at the intersection of the hardenability curve and the selected bar size and section-location curves. In Fig. 16 point A indicates that the center of a 1-in. round of this heat of S.A.E. 1040 steel would have a hardness of approximately 38 Rockwell C when quenched in water. To find the anticipated hardness halfway between the surface and the center, the correlation chart is moved up until the junction of the half-radius and 1-in. curves intersects the hardenability curve. Here a hardness of 48 Rockwell C is obtained. The oil-quench correlation chart is used in a similar manner.

These correlation charts permit the rapid translation of hardenability data to cross-sectional hardness data for various tempering temperatures as well as the as-quenched values by using tempering curves like those appearing in Figs. 12 and 13. They also permit the rapid determination of hardness depth for incompletely hardened parts and the establishment of limiting size of a given steel for a particular quench when a minimum acceptable hardness has been decided upon.

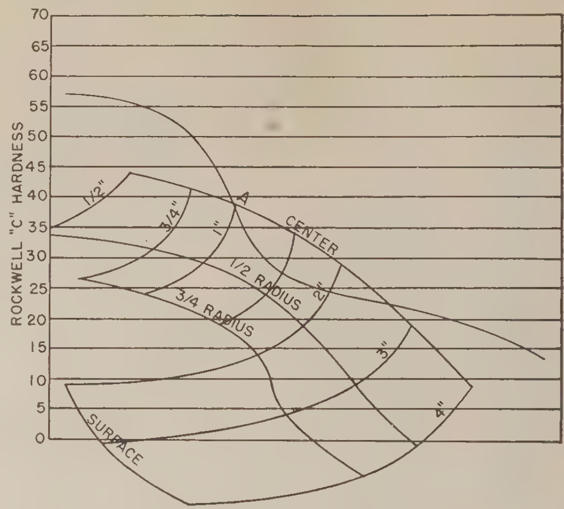

Fig. 16 Use of Water-Quench Correlation Chart on End-Quench Hardenability Curve for an S.A.E. 1040 Steel

Elevated-Temperature Stretch-Flanging of Some Aluminum Alloys

By E. G. Thomsen,[1] D. M. Cunningham,[2] and J. E. Dorn[3]

Many aircraft parts consisting of a flat web and a concave flange are produced by rubber-die-forming on a hydropress. The forming action consists of bending the flange around the die radius and stretching the outer fiber of the flange from its original length to that which is achieved when it contacts the die. Several types of failures and defects are encountered, the most important being a radially directed fracture initiated at the outer fiber of the flange. When this fracture occurs without necking, the maximum per cent stretch that may be produced approximates the per cent local ductility in the tension test. If, however, fracture is preceded by necking, the permissible per cent stretch is intermediate between the uniform and local per cent strain in tension. Increasing the forming temperature permits greater per cent stretches for some of the more-ductile alloys.

Introduction

Many aircraft parts consist of a flat web with a concave flange. Such parts are usually produced by rubber-die-forming on a hydropress at atmospheric temperature. Although many aircraft materials exhibit ample deformation to permit successful forming of concave flanges, other materials, particularly those in the aged condition, have such limited deformability that satisfactory flanges cannot be produced. The Western Aircraft War Production Council recommended that the War Metallurgy Committee investigate the mechanics of concave flanging and the possibilities of improving this operation by forming at elevated temperatures. This report is based on investigations conducted by Project NRC-548 for the Office of Production Research and Development of the War Production Board.

The rubber-die hydropress-forming of concave flanges has been described in several papers.[4,5,6] A blank of radius R_b, as illustrated in Fig. 1, is placed on a die block having a contour radius R_c somewhat greater than R_b. As the rubber contained in the head of the press is impressed against the die, the blank is bent around the die radius along the die contour line until the formed flange touches the die. Since the extreme fiber of the flange is stretched from a radius R_b to the larger radius it assumes when contact is achieved, the operation is commonly called stretch-flanging.

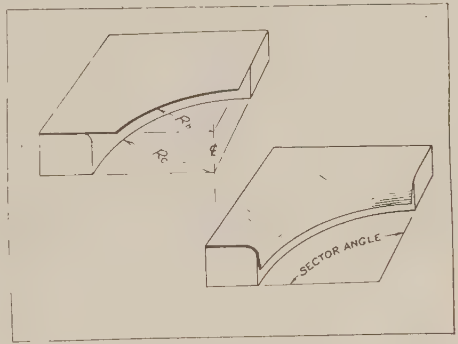

Fig. 1 Blank and Flanged Part of Die

Experimental Procedure

Scope of Investigation. Tests were planned to determine the stretch-flanging limits of a number of aluminum-alloy sheet materials at forming temperatures of 70 F, 300 F, 400 F, and 450 F. The maximum temperature of 450 F was selected because of rapid deterioration of the rubber pad at higher temperatures and possible detrimental changes in physical properties of some of the precipitation-hardened alloys. The general survey of the effect of temperature on the stretch-flange formability was carried out on a 4-in-contour-diam die with blanks having 360-deg flange sectors. Spot tests were made on other variables, such as other contour diameters, sheet thicknesses and sector lengths, in order to observe the major trends introduced by these variables.

Materials. The standard aluminum sheet materials that were investigated included 3S-O, 52S-O, 24S-O, 61S-O, 75S-O, 24S-T, 24S-T86, 61S-T, R301-T, and 75S-T covering thicknesses from 0.020 in. to 0.081 in.

Equipment. The hydropress consisted of a modified 200-ton aircraft-type press. The platen was 15 in. wide and 28 in. long arranged with electric-resistance heaters and automatic temperature control.

The normal platen pressure was 1050 psi, but pressures as high as 7000 psi were obtained with special platens and rubber heads. The mild-steel die blocks had contour diameters of 3, 4, 6, and 8 in.; $^3/_{16}$-in. bend radii were provided on all dies in order to eliminate bend failures.

Specimens. The specimens were sheared from sheet stock with die-locating holes and blank pilot center hole jig-drilled. The desired blank-hole diameter was machined with a fly cutter to an accuracy of 0.010 in. of the nominal blank-hole diameter. All blank holes were polished with 2/0 Behr Manning polishing paper after machining, in order to provide uniformly controlled edge conditions.

Experimental Technique. The specimen blanks were preheated to the forming temperature for 10 min in an air furnace and rapidly transferred to the die block. A light layer of asbestos powder was screened over the blank in order to prolong the useful

life of the rubber pad. The press head was then moved against the platen to a predetermined pressure which permitted complete forming of the blank. A series of blanks were thus formed with blank-hole diameters varying in steps of 0.10 in. (flange widths varying in 0.05-in. steps). The critical blank diameter was evaluated as the minimum diameter that was successfully formed. Frequently in the region of the critical diameter a specimen would fracture, whereas a duplicate specimen would form successfully. In this case the critical value of blank diameter was taken as the larger and more conservative value.

In order to obtain forming temperatures in the blank approaching those of the die it was necessary to hold the blank under light pressure for 1 min between rubber pad and heated die before forming the stretch flange. All temperatures reported herein are those of the heated die but represent the blank temperature to within 10 deg F.

Geometry of Stretch Flanges. The simplest type of stretch flange consists of a 360-deg sector produced on a block having a 90-deg die angle. For this type flange the per cent stretch of the outer fiber of the flange is simply

$$\text{Per cent } S = \frac{(R_e - R_b)}{R_b} \times 100 \ldots\ldots\ldots\ldots [1]$$

As smaller values of R_b are employed the per cent stretch of the outer fiber of the flange increases. Finally a critical value is reached resulting in fracture of the flange. The maximum permissible stretch is given by

$$\text{Per cent } S_{max} = \left(\frac{R_e}{R_{b\ min}} - 1\right) \times 100 \ldots\ldots [2]$$

and the corresponding true strain is

$$\phi_{max} = \ln \frac{(R_e)}{R_{b\ min}} \ldots\ldots\ldots\ldots\ldots\ldots [3]$$

If the sector angle is less than 360 deg, another geometrical factor enters the analysis. The induced circumferential tensile stresses causing stretching vanish at the sector edges and the per cent stretch that is obtained becomes less than the value calculated from Equation [1]. The actual stretch is therefore less than the theoretical stretch, and consequently flanges of greater heights may be produced without encountering failures.

For small sector angles, the arc length of the flange approaches the corresponding chord length. Since the energy that is required to form a straight flange is less than that required for a curved flange of the same contour length, flanges of small sector angle frequently form straight flanges along the chord.

In order to produce a part having a flange at 90 deg to the web, the part must be slightly overformed so that the desired angle is obtained after springback. The per cent stretch for dies having angles that differ from 90 deg is derived in Appendix 1.

Experimental Results

Types of Fracture. The forming of stretch flanges is limited by several forming defects and failures which are shown in Fig. 2, and are briefly described as follows:

(*a*) *Stretch Rupture.* Stretch rupture, illustrated in Fig. 2(A), is the most common type of forming failure. This type of fracture was encountered in most of the 360-deg flanges that were tested. Two types of fracture were observed. The annealed alloys at all temperatures and some of the precipitation-hardened alloys at 450 F exhibited local necking preceding fracture; some of the precipitation-hardened alloys fractured without necking at the lower temperatures.

(*b*) *Bulging Rupture.* The second type of rupture which limits the formability is shown in Fig. 2(B), and was named a bulging rupture. This type of rupture was obtained when small blank-hole diameters were employed. Instead of forming a flange the blank bulged in a manner similar to that obtained in the absence of a central hole. Fracture occurred along the die-contour radius before the outer fiber reached its limiting ductility. This type of fracture was not obtained when the hole diameter was increased to the critical value for stretch rupture.

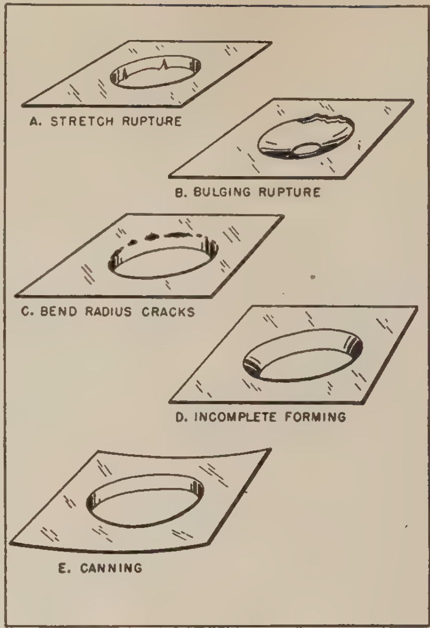

Fig. 2 Forming Defects

(*c*) *Bend Cracks.* If the die bend radius is too small the strains of the fiber on the top surface of the blank may exceed the permissible strain before the outer fiber of the flange reaches its critical stretch value, resulting in fracture of the upper surface of the blank along the die bend radius. This type of fracture is shown in Fig. 2(C). In the present investigation the die bend radii were maintained sufficiently large to prevent the formation of bend cracks.

(*d*) *Incomplete Forming.* In forming stretch flanges the blank is bent as well as stretched. Consequently the pressure required for forming stretch flanges is greater than that required for straight flanges. If the pressure is not great enough an incompletely formed flange results, as shown in Fig. 2(D). The pressures for the present investigation were maintained sufficiently large to insure contact of the outer fiber of the blank and the die.

(*e*) *Canning.* Canning, as shown in Fig. 2(E), results from springback after forming. No attempt was made to evaluate completely the springback after forming, but it was observed that the springback for stretch flanges is slightly less than that for straight bends for the same conditions of forming temperature, sheet thickness, and bend radius.

Maximum Per Cent Stretch. The effect of temperature on the maximum per cent stretch that may be achieved in a number of aluminum alloys is shown in Fig. 3. It is evident from these curves that increased stretch-flange formability is achieved at temperatures above 300 F for all alloys investigated. Each alloy, however, exhibits its own peculiar maximum per cent stretch-temperature curve.

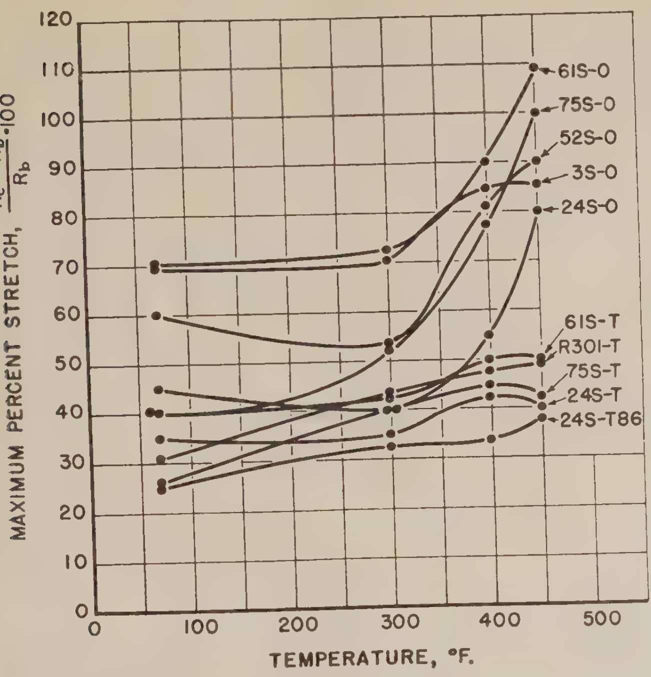

FIG. 3 EFFECT OF TEMPERATURE ON MAXIMUM PER CENT STRETCH

A few tests were made to evaluate the effect of contour radius on the maximum per cent stretch. Materials which necked during flanging yielded decreasing per cent stretch with increasing contour radii.

The effect of thickness was studied for 24S-O and 61S-T formed at atmospheric temperature on a 6-in-contour-diam die. Slightly greater per cent stretch was observed as the thickness was increased from 0.020 to 0.081 in., but results were too varied to warrant a more definite statement.

The effect of the angle of sector of the blank on the maximum per cent stretch is given in Fig. 4 for atmospheric and 450 F forming temperatures. The plain open and solid circles refer to maximum per cent stretch limited by stretch fracture, whereas the crossed symbols refer to maximum per cent stretch limited by fracture at the edge of the segmented blanks near the die bend radius. For the two alloys investigated the maximum per cent stretch with atmospheric-temperature forming rises moderately with decreasing sector angle to a maximum at approximately 90 deg. Blanks with sector angles of 30 deg could not be fractured at all forming temperatures. At 450 F alloy 24S-O could not be fractured with sector angles of 90 deg or less.

Discussion of Results. A major objective of investigations on the formability of metals is the development of a useful philosophy that will permit the prediction of forming limits from a few simple, easily obtainable test data. Most metal-forming processes, however, are so complex that this objective has not been completely achieved; stretch flanging is not an exception. The results of this investigation, however, show that the forming limit for stretch flanges can be approximated in a few simple cases.

The fracture causing a stretch-rupture failure during forming starts at the outer fiber of the flange. Although, in some alloys, local plastic action precedes fracture in this critical region, in other alloys fracture occurs without evidence of necking. Many alloys that neck when tested in simple tension do not neck when stretch-flanged.

An estimate of the maximum per cent stretch is possible for alloys that do not neck when stretch-flanged. Since the outer fiber of the flange is known by grid analyses to be essentially stressed by simple circumferential tension, it is logical to assume that stretch rupture is initiated when the circumferential tension stress equals the true fracture stress in tension. This assumption implies that the maximum true strain for stretch-flange forming should approximate the true local strain in tension defined by

$$\phi_{\max} = \ln \frac{A_0}{A_f}$$

where

A_0 = original cross-section area
A_f = cross-section area at fracture

A comparison of the maximum true stretch with tension data,[7] obtained from standard A.S.T.M. specimens, shown in Fig. 5, illustrates the agreement that may be expected. Materials 24S-T86 at all temperatures, R301-T and 75S-T up to 300 F, and 24S-T up to 400 F exhibited stretch ruptures without evidence of necking. For these conditions the maximum true stretch approximated the true local strain in tension. In all other cases necking preceded fracture, and the maximum true stretch that could be achieved was intermediate between the true uniform and the true local strains in tension. Thus the maximum true stretch that can be achieved in the absence of necking approaches the true local strain at fracture in tension.

No satisfactory analysis is available for predicting the stretch-flange-forming limits of materials under conditions where necking is obtained; the maximum true stretch is significantly greater than the true uniform strain in tension. Since necking is known to begin when the resistance to the forming load passes a maximum value, it is logical to suspect that necking in stretch-flanging requires a complete analysis of the stress and strain distribution in the entire flange. Thus changes in contour diameter may affect

FIG. 5 COMPARISON OF STRETCH-FLANGING DATA WITH TENSILE DATA

the per cent stretch. The complex distribution of stresses in the flange are not yet known and therefore complete knowledge of stretch-forming limits will have to await the development of this involved analysis.

SUMMARY AND CONCLUSIONS

1 Forming of 360-deg-sector stretch flanges in a number of aluminum alloys is limited by stretch rupture, radius-bend cracks, or available press pressure.

2 Materials 24S-T, 24S-T86 and 75S-T fractured without evidence of necking when formed at 70 F to 300 F; for all remaining materials and temperatures investigated, fracture was preceded by necking except R301-T at 70 F.

3 The maximum per cent stretch obtained with 24S-T, 24S-T86, and 75S-T agrees closely with the local ductility in tension when formed at temperatures of 70 F to 300 F; between 300 F and 450 F some necking preceded fracture.

4 The maximum per cent stretch for 3S-O, 52S-O, 24S-O, 61S-O, 75S-O, and 61S-T falls between the local and the uniform per cent strain in tension for all temperatures investigated.

5 Higher stretch-flange-formability may be achieved with a 3-in. than with an 8-in-contour-diam die at a forming temperature of 70 F for alloys 24S-O and 61S-T.

6 Increasing thickness from 0.020 in. to 0.064 in. results in higher stretch-flange-formability for alloys 24S-O and 24S-T when formed on a 6-in-contour-diam die and 70 F.

7 Sectors may be formed to a greater flange height than 360-deg flanges for 24S-O and 24S-T.

8 Springback of stretch flanges is slightly less than for straight bends for the same die radius and sheet thickness.

ACKNOWLEDGMENT

The authors wish to acknowledge the support of the Office of Production Research and Development of the War Production Board on this investigation. They are particularly indebted to the Western Aircraft War Production Council for suggestions and assistance in planning this investigation. The authors also wish to thank Messrs. T. Robinson, V. Gudmendsen, and Miss Barbara Roney, for their assistance on the experimental phases of the investigation.

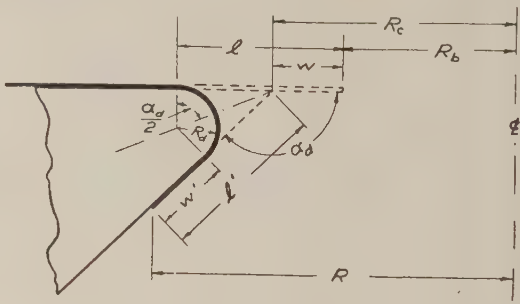

FIG. 6 GEOMETRY OF STRETCH FLANGE

Appendix 1

PER CENT STRETCH FOR 360-DEG FLANGES

Assuming that the changes in thickness and length are minor, an approximate calculation of the effect of the die angle on the stretch is readily obtainable from Fig. 6.

Let

$$l' = w' + R_d \tan\frac{\alpha_d}{2}$$

$$w' = l - \alpha_d R_d$$

$$l' = l - \alpha_d R_d + R_d \tan\frac{\alpha_d}{2}$$

$$l = w + R_d \tan\frac{\alpha_d}{2}$$

$$l = R_c - R_b + R_d \tan\frac{\alpha_d}{2}$$

$$l' = R_c - R_b + R_d \tan\frac{\alpha_d}{2} - \alpha_d R_d + R_d \tan\frac{\alpha_d}{2}$$

$$R = R_c - l'\cos\alpha_d = R_c - \left[R_c - R_b + R_d\left(2\tan\frac{\alpha_d}{2} - \alpha_d\right)\right]\cos\alpha_d$$

$$\text{Per cent } S = \left(\frac{R - R_b}{R_b}\right)\cdot 100 = \left[\left(\frac{R_c}{R_b} - 1\right)(1 - \cos\alpha_d) - \frac{R_d}{R_b}\left(2\tan\frac{\alpha_d}{2} - \alpha_d\right)\cos\alpha_d\right]\cdot 100$$

Accordingly, the true strains of the outer flange fiber are

$$\phi = \ln\frac{R}{R_b} = \ln\left[\frac{R_c}{R_b} - \left\{\frac{R_c}{R_b} - 1 + \frac{R_d}{R_b}\left(2\tan\frac{\alpha_d}{2} - \alpha_d\right)\right\}\cos\alpha_d\right]$$

Actually, the length l' is somewhat smaller than assumed in the foregoing analysis owing to simultaneous thinning of material and shortening of the flange during stretching. Usually this factor may be neglected, as it is generally a small correction term.

Folding in Tube-Sinking

By GEORGE SACHS[1] and W. M. BALDWIN, JR.[2]

An experimental study of the folding tendency of tubes during the process of sinking was made. It was determined that tubes with a fold-free point, having a wall thickness of less than 1 per cent of the diameter, can be sunk without folding. However, if it is attempted to sink tubes with points containing folds beyond a certain critical reduction, the fold contained in the point will be perpetuated throughout the length of the tube. This critical reduction increases almost linearly with the ratio of thickness to diameter of the tube, and is little affected by the die angle, the metal, and its temper. The length of the fold during its formative period is found to increase with increasing reduction, with decreasing relative thickness, and to be relatively unaffected by die angle. The stress required to sink a tube with folds was found to increase only slowly beyond the limiting stress for sinking such a tube without folding to the smallest possible diameter.

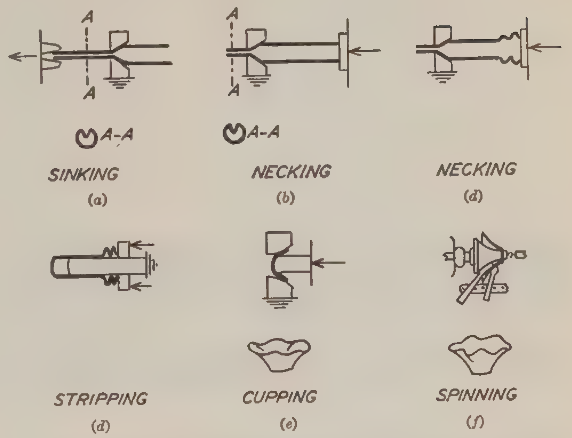

Fig. 1 Various Industrially Important Plastic-Forming Operations in Which Folding Can Occur

Nomenclature

The following nomenclature is used in the paper:

A = cross-sectional area of tube
D = mean diameter of tube
L = gage length of tube
P = force required to sink tube
s_1 = average longitudinal tension in sinking
t = wall thickness of tube

Note: o as a superscript refers to original dimensions. Primed symbols refer to final dimensions.

Introduction

Certain metal-forming operations are performed in such a manner that the metal is not completely constricted in its flow by the forming tools, with the result that the metal may escape the desired or intended shaping by buckling or folding. Of these operations, the following are industrially important:

"Sinking," where a tube is drawn through a die without support on its internal surface. Circumferential or hoop stresses may cause the tube to fold along its length if the wall of the tube is thin, Fig. 1 (*a*).

"Necking," "tapering," and "nosing," where a tube is pushed through a die without internal support. In this case the tube may fold along its length, Fig. 1 (*b*), but may also develop transverse folds under the action of longitudinal stresses, Fig. 1 (*c*).

"Stripping," where a shell or cup is removed from a draw punch. The cup is supported on its internal surface by the punch but not on its exterior surface. The longitudinal compressive stresses may therefore develop transverse folds, Fig. 1 (*d*).

"Cupping," or "deep drawing," where a blank is pushed by a punch through a die, forming a cup or shell. The sheet cannot always be supported sufficiently by holddown pads to prevent radial wrinkles or creases caused by compressive hoop stresses, Fig. 1 (*e*).

"Spinning," where a sheet is rotated in a lathe while forming tools work the sheet onto a forming block to produce a cup. Circumferential stresses again can develop radial wrinkles, Fig. 1 (*f*).

These folds and wrinkles appear to be specific cases of the general class of buckling failures and as such are characterized by two features: (*a*) they occur in "slender" articles, i.e., in thin metal, and (*b*) they are caused by compressive stresses lying in the plane of the sheet or the wall of the tube and acting in a direction normal to that in which the fold occurs.

The only one of the phenomena described which has been made the subject of theoretical considerations is the wrinkling of a deep-drawn cup (1).[3] However, this analysis has been applied principally in predicting the number of waves into which the flange would buckle rather than to the limiting conditions under which the cupping operations could be successfully conducted.

In the present work the factors involved in the folding or collapsing of tubes being sunk will be studied experimentally. The variables studied will be the alloy, its temper, the wall thickness of the tube, and the die contour.

Materials and Procedure

For the experimental investigation tubes of four different materials were used: (*a*) hard phosphorus-deoxidized copper (Rockwell 30-T, 59–66); (*b*) soft phosphorus-deoxidized copper (annealed 1 hr at 1000 F in a forced-convection furnace); (*c*) soft tube brass (66.5 per cent copper, 0.5 per cent lead, balance zinc, annealed 1 hr at 1000 F); and (*d*) soft aluminum (2S, annealed 15 min at 600 F).

The tubes were drawn commercially to different diameters ranging from 0.580 to 1.375 in., and possessed a wall thickness

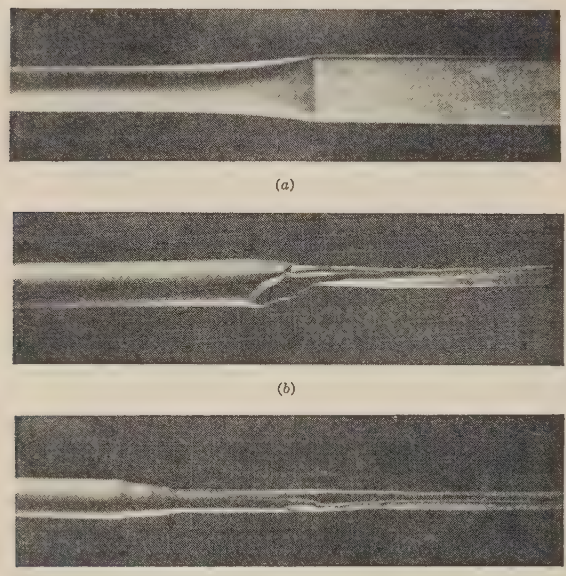
varying between 0.009 to 0.050 in. In the case of the hard copper, the reduction in cross-sectional area after the last anneal (but before sinking) was approximately 50 per cent.

Tube specimens, approximately 40 in. long, were drawn through three different sets of conical steel dies, possessing half die angles of 7, 14, and 27 deg, respectively, to an outside diameter ranging from 0.375 to 1.300 in. The polish on the 7-deg die was inferior to that of the 14- and 27-deg dies.

Two types of points were put on the tubes, i.e., a folded point and a fold-free point. The first type of point was obtained by first flattening the tube, and then folding the flattened section under as shown in Fig. 2 (a and b). The fold-free point was obtained by sinking a tube progressively with a folded point in sufficiently small steps for a short length of the tube to eliminate the fold, Fig. 2 (c).



(a)

(b)

(c)

Fig. 2 Procedure of Pointing Tube

(a, Flattened tube end. b, Flattened section folded under. c, Tube drawn in a series of small reductions which eliminates folds and produces "fold-free" point.)

The sinking was performed on either an Olsen 60,000-lb, or a Baldwin Southwark 100,000-lb tensile-testing machine, at a speed of approximately 0.5 fpm. For this purpose a special die holder was attached above the upper jaw of the testing machine and the point of the tube was gripped and pulled with the regular lower jaw. A commercial soap-base lubricant with a high free-fat content (Nopco No. 6) was employed.

The load required to sink the tube was generally found to remain constant within ± 5 per cent over the entire length of each tube.

Micrometer measurements were made on both the initial and the drawn tube in order to compute the sinking stress s_1, and the reduction in mean diameter, D. The sinking stress was calculated from the formula

$$s_1 = \frac{P}{A'} = \frac{P}{\pi t' D'}$$

The significant strain for the strain-hardening of the metal in tube-sinking is the reduction in mean diameter for those cases where the wall thickness increases during the operation. This was the case for all tubes investigated since in no instance did the ratio of the wall thickness to mean diameter exceed 0.05, at which value, according to Baldwin and Howald (2), the wall thickness increases for reductions in outside diameter as high as 50 per cent.

This reduction in mean diameter R was computed by means of the equation

$$R = 1 - \frac{D'}{D}$$

The relative thickness of a tube is defined in the present work as the ratio of the wall thickness of the tube to the mean diameter of the tube, t^0/D^0.

If no restriction were put on the angle at which the tube entered the die, the tube would assume a cant, especially with the heavier drafts, when a fold was being perpetuated, Fig. 3. In general, the cant was toward the fold when the tube was sunk through wide-angle dies, whereas the tube assumed a cant away from the fold in the case of the narrow-angle die, although there were a few exceptions to this general rule. Experiments conducted with a restricting cage to force the tube into an axial position, however, showed that this factor had a negligible effect on the critical reductions that could be made.

Theory of Folding

The folding during tube-sinking and the closely related process of necking (primarily observed in cartridge cases) are, according to all external appearances, phenomena of plastic buckling, Figs. 12 to 14, inclusive. The stress responsible for folding is clearly the compressive hoop stress. This hoop stress varies for a fold-free tube along the length of the tube portion in the die, being determined for a given material primarily by the reduction from the original to the considered cross section.

If certain unknown conditions, regarding the magnitude and distribution of the hoop stresses required to draw a fold-free tube, exist the tube wall would be expected to collapse. It was therefore believed at the beginning of this investigation, that folding during tube-sinking might be closely related to the collapsing of a tube under external pressure. In any buckling process one of the decisive factors is the metal thickness; and the expected effect of wall thickness was also found to occur in folding, as discussed later. In the case of collapsing, increasing length of the portion exposed to pressure reduces the unit collapsing pressure (3, 4, 5, 6). The conclusion to be drawn from this fact, that a sunk tube drawn with an acute die (i.e., a long contact length) should collapse after a smaller reduction than a tube drawn through a large-angle die, has not been verified by the following experimentation.

In addition, it was found that no folds could be obtained within the limits of the investigated dimensions without the presence of a preformed fold. Therefore the phenomenon of folding probably is not related to a true buckling process, but comprises a new problem of plastic flow. The results of this investigation may help to reveal the nature of this problem, which, of course, must be recognized before any theoretical analysis can be attempted.

Experimental Results

Sinking of Tubes With a Fold-Free Point. As already mentioned, it was not found possible to collapse any tube with a fold-free point. The circular contour appears to be highly resistant to buckling, even in tubes with the thinnest wall and subjected to the highest possible reduction. An extreme example was soft-copper tube with $D^o = 1$ in. and $t^o = 0.009$ in. (i.e., a ratio $t^o/D^o = 0.009$) and a reduction in mean diameter of approximately 50 per cent.

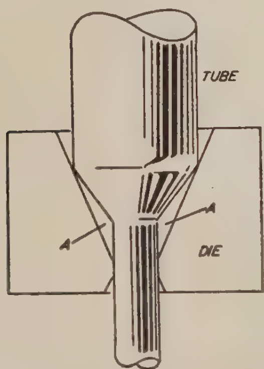

Fig. 4 Entrapment of Lubricant Between Tube and Die
(If the tube was prepared with a fold-free point whose angle was greater than that of the die, the lubricant could be entrapped in the cavities A-A. Being incompressible, it would force folds into the tube being sunk.)

Such fold-free tubes, however, are obtained only if the tubing is free from dents, and seams. In addition, it was observed that any lubricant entrapped between the die and tube surface caused folding, as illustrated schematically in Fig. 4.

The same facts were found also to exert a considerable influence in the necking of cartridge cases. A high percentage of rejections encountered in regular production was eliminated in one instance by avoiding any denting on handling the mouth of annealed cases, and in another case by designing the die contour such that no lubricant was entrapped in successive tapering operations.

Conditions for the Development of Folds in Sunk Tubing. Either one of two cases occurred when drawing a tube with a folded point: When subjected to small reductions in diameter, the resulting tube was fold-free, while beyond a certain reduction it folded along its entire length. Close to this limiting reduction the fold was eliminated only after the tube was drawn for a considerable length, occasionally as much as 12 in.

In the case of a tube which contained folds when sunk, the reduction in mean diameter possesses no physical significance. In order to evaluate the data, however, it is necessary to know what reduction could have been attained if folding had not occurred.

(Data for 25-deg dies.)

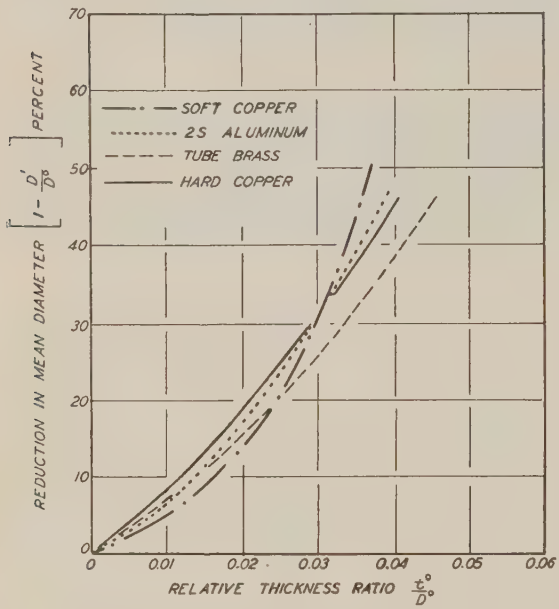

FIG. 7 LIMITING REDUCTION TO WHICH TUBES OF DIFFERENT METALS MAY BE SUNK USING FOLDED POINTS
(Data for 14-deg dies.)

This intended reduction was obtained by interrupting the sinking process, which produced folds; preparing the tube with a fold-free point; and then resuming the sinking process without folding. The (intended) reduction was then taken as that of the fold-free tube.

A typical set of experimental data is represented in Fig. 5. It assembles the results obtained on tubes of varying wall thickness of a particular alloy and drawn through a particular die. A solid line has been drawn separating the conditions where a fold was perpetuated in the sinking process from those conditions where folds are eliminated. This graph illustrates the degree of accuracy in determining the dividing line between folded and fold-free tubing. In general, the position of this line appears to be accurate within approximately ±3 per cent reduction.

In Figs. 6 to 8, inclusive, all the experimentally determined boundary lines are shown for the three different dies, the various curves in each graph belonging to the different alloys. These graphs illustrate that the reduction in mean diameter, up to which a tube can be sunk fold-free depends primarily upon the relative thickness of the tube. In general, it increases slightly faster than proportional to the reduction, for all conditions investigated. Any one of the investigated alloys could be sunk with any one die to the commercial reduction limit of approximately 50 per cent, if the wall thickness is larger than 5 per cent of the outside diameter. On the contrary, no tube investigated possessing a wall thickness of approximately 1 per cent of its diameter could be drawn fold-free (with a folded point) by more than approximately 10 per cent reduction.

This relation was found to be comparatively independent of either the alloy, according to Figs. 6 to 8, inclusive, or the die angle, according to Figs. 9 to 11, inclusive. A possible effect of the alloy, exceeding the accuracy limits of experimentation, was observed only for the wide-angle 27-deg die. Contrary to expectations for a buckling phenomenon, hard copper could be sunk fold-free to higher reductions than soft copper.

Also, regarding any effect of die angle, it could have been expected that a large-angle die, because of its length of contact, would permit larger reductions than an acute die. Numerous investigations on the collapse of tubes when subjected to external pressure reveal a profound effect of specimen length on collapse pressures (3, 4, 5, 6). It would normally be expected that this effect would apply to tube-sinking if the fold development was a phenomenon of buckling.

Observations on Fold Development. This anomalous behavior

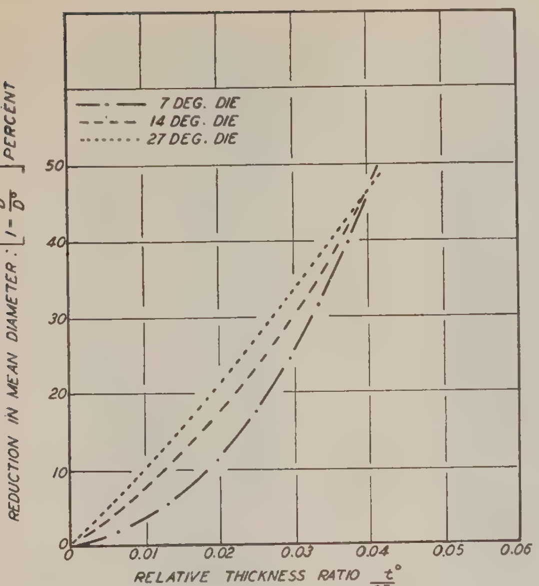

Fig. 9 Limiting Reduction to Which Soft 2S Aluminum May Be Sunk Using Folded Points

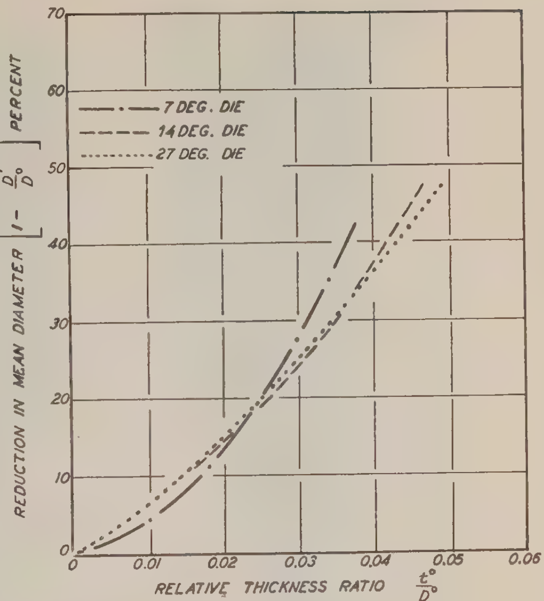

Fig. 10 Limiting Reductions to Which Soft Tube Brass May Be Sunk Using Folded Points

is more readily understood, however, if the geometry of the fold is studied. The manner in which the fold is perpetuated along the length of the tube is illustrated in Figs. 12 to 14, inclusive. The point of inception of the fold is shallow, but as the metal proceeds through the die, the fold deepens generally, first becoming broader and then narrower. When the metal leaves the die the edges of the fold are brought together. This cycle occurs for all reductions, heavy or light. The length of the fold depends primarily upon two factors, i.e., the intended reduction Fig. 12, and the relative thickness, Fig. 13. It is, however, practically independent of the die angle, other factors being constant, Fig. 14. Consequently, the point of inception of the fold may be either inside or outside of the die. It appears interesting that the die contour, and consequently the length along which the forces act, which cause the reduction in diameter, has practically no effect on the fold development.

The length of the fold was measured for a number of soft copper tubes drawn through the 27-deg die, Fig. 15. The critical reductions for the various relative thickness ratios have been also entered in Fig. 15, as arrows. It is seen that the length of fold at the critical point is roughly equal to the diameter of the initial outside diameter.

In fold-free sinking the reduction in diameter causes the length of the tube to increase, while the thickness remains practically constant, as mentioned previously. If the formation of a fold were merely a matter of the tube wall being folded into a lobe as the tube was drawn through the die, little change in the cross-sectional area of the original tube would be anticipated. The reduction in diameter would then cause primarily a bending in the area containing the fold, while the remaining portion of the cross section would be only slightly curved. Such a process would result in no change in length of the tube. Some measurements, however, reveal that during the sinking of a folded tube the cross-sectional area is definitely reduced and that, consequently, the entire cross section is subjected to plastic flow.

To determine any increase in length, 2-in. intervals were scribed along the length of tubes. The tubes were sunk with folds, and the segments were then measured. From the assumption that the volume of the metal remains constant during plastic deformation, the ratio of the initial length to the final length of a tube section yields the reduction in cross-sectional area affected by the process

ter). It is apparent that an increase in both the intended reduction and the relative thickness ratio of the tube leads to an increase in the actual reduction in area.

Thickness measurements revealed that no thickness changes occur before the folded tube enters the die. Within the die, however, the wall thickness increases. As shown in Fig. 17 this deformation is not uniform around the circumference as the wall thickens to the greatest extent at a point diametrically opposite to the fold.

Stresses to Sink Folded Tubes. The unit stress s_1, required to pull the folded tube through the die is determined by the equation

$$s'_1 = \frac{P}{A'} = \frac{P}{A^\circ}\frac{L'}{L^\circ}$$

In Fig. 18 the stresses required to sink (with folds) brass tubes of various initial relative thickness ratios, through a 14-deg die, are plotted as a function of the intended reduction. It is to be noted that the curves so obtained intersect the curve for sinking without folds, reported previously (7), at the critical reduction, for the relative thickness ratio in question.

The curves for various relative thickness ratios can be further reduced to a single master curve if the values for the individual stresses are divided by the relative thickness ratio. This has been carried out in Figs. 19 and 20 for tube brass and hard copper, respectively.

Conclusions

The results of this investigation cannot be reconciled with the conventional theory of buckling or collapsing. The factors which determine the perpetuation or elimination, respectively, of a fold in tube-sinking are different from those which determine definite buckling phenomena such as the collapsing of a tube.

The only factor which is conducive to both collapsing and fold formation is a small thickness-to-diameter ratio. Other factors, however, such as the length along which pressure is applied and the elastic and plastic metal properties which are important in collapsing, have only a minor influence on folding.

The predominant effect of the reduction in diameter cannot be satisfactorily explained. However, it has been observed that a fold is enlarged only if the circumferential force is smaller for this process than for fold-free sinking, assuming that the differences in the respective sinking forces also indicate proportional differences in the circumferential forces, other conditions being equal. This would also explain the observation that if the sinking forces for folded tubes equal those for fold-free tubes, the tendency to fold disappears. In other words, a fold will be perpetuated only if the resistance against bending into the fold is smaller than the resistance against a uniform compression of the diameter. No theoretical approach to this phenomenon has been developed as yet.

It has been also observed that it is much more difficult to obtain a fold on sinking a circular cross section than on sinking a section with a preformed fold. This result may be compared with the buckling forces required to deform permanently bars under concentric and eccentric loading, respectively.

Stress Analysis of Tube-Sinking

By GEORGE SACHS,[1] AND W. M. BALDWIN, JR.[2]

A theoretical stress analysis was made of the tube-sinking operation, equations being set up to yield the sinking stress as a function of the reduction in mean diameter. The equations were confirmed by experimentation on annealed and full hard copper and on annealed tube brass for conical dies of various tapers. The coefficients of friction existing during tube-sinking have been determined and are found to be of the same magnitude as those determined previously for wire drawing.

Nomenclature

The following nomenclature is used in the paper:

A = cross-sectional area of tube

B = parameter $= \dfrac{\tan\alpha + f}{\tan\alpha}$

D = mean diameter of tube

f = friction coefficient

k = flow stress (or yield strength in tension)

k_0 = $1.1\,k$

P = force required to sink tube

s_1 = algebraically largest principal stress, assumed to be average longitudinal tension in sinking

s_2 = intermediate principal stress, assumed to be die pressure

s_3 = algebraically smallest principal stress, assumed to be average hoop stress

t = wall thickness of tube

x = longitudinal co-ordinate

α = angle between die wall and tube axis = half die angle of conical die

NOTE: o as a superscript refers to original dimensions. Primed symbols refer to final dimensions.

Introduction

The analysis of the stresses occurring in a number of forming processes, in which the metal is continuously subjected to deformation, follows in each case a similar pattern. The processes to which such an analysis has been applied so far, wire-drawing (1, 2),[3] strip-rolling (3, 4, 5, 6, 7), and tube-drawing with a moving mandrel (8) have one feature in common, namely, that the mean stresses acting on each cross section can be derived from the equilibrium of the longitudinal forces.

An analysis of tube-sinking has not been attempted previously. In a paper dealing with the stress and strain relations in tube-sinking, it was assumed that the stresses in this process are identical with those occurring in wire-drawing (9).

The following discussion presents a theoretical and experimental analysis of the tube-sinking process. In order to develop a differential equation for the stresses occurring in the process, it was found necessary to consider not only the equilibrium of the longitudinal but also that of the transverse forces. This results from the fact that in contrast with the processes just mentioned the largest and smallest principal stresses in tube-sinking do not occur in a longitudinal plane but in a circumferential plane.

In the experimental analysis, the high tendency of the tube being sunk to develop folds was eliminated by a special pointing procedure. This yielded a fold-free point, which permitted sinking operations with tubes with the smallest available wall thickness to maximum reductions without folding, and thus to measure the sinking forces over a wide range of conditions. The problem of folding will be considered in a subsequent publication.

Materials and Procedure

For the experimental investigation, tubes of three different materials were used: (*a*) hard phosphorus-deoxidized copper (Rockwell 30-T, 59–66); (*b*) soft phosphorus-deoxidized copper (annealed 1 hr at 1000 F in a forced-convection furnace); and (*c*) soft tube brass (66.5 per cent copper, 0.5 per cent lead, balance zinc, annealed 1 hr at 1000 F). The tubes were drawn commercially to different diameters, ranging from 0.580 to 1.375 in., and possessed a wall thickness of 0.015 to 0.050 in. In the case of the hard copper, the reduction in cross-sectional area after the last anneal (but before sinking) was approximately 50 per cent.

Tube specimens, approximately 40 in. long, were drawn through three different steel dies, possessing half die angles of 7, 14, and 27 deg, respectively, to an outside diameter of 0.50 in. The polish on the 7-deg die was inferior to that of the 14- and 27-deg dies.

The sinking was performed on either an Olsen 60,000-lb, or a Baldwin Southwark 100,000-lb tensile-testing machine, at a speed of approximately 1/2 fpm. For this purpose, a special die holder was attached above the upper jaw of the testing machine, and the point of the tube was gripped and pulled with the regular lower jaw. A commercial soap-base lubricant with a high free-fat content (Nopco No. 6) was employed.

The load required to sink the tube was generally found to remain constant within ±5 per cent over the entire length of each tube.

Micrometer measurements were made on both the initial and the drawn tube in order to compute the sinking stress s_1', and the reduction in mean diameter. The sinking stress was calculated from the formula

$$s_1' = \frac{P}{A'} = \frac{P}{\pi t' D'}$$

The significant strain for the strain-hardening of the metal in tube-sinking is the reduction in mean diameter for those cases where the wall thickness increases during the operation. This was the case for all tubes investigated, since in no instance did the ratio of the wall thickness to mean diameter exceed 0.05, at which value, according to Baldwin and Howald (10), the wall thickness increases for reductions in outside diameter as high as 50 per cent.

The reduction in mean diameter R was computed by means of the equation

$$R = 1 - \frac{D'}{D^o}$$

[3] Numbers in parentheses refer to the Bibliography at the end of the paper.

Contributed by the Metals Engineering Division and presented at the Spring Meeting, Chattanooga, Tenn., April 1–3, 1946, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

Stress-strain curves by means of tensile tests were determined for the various metals before and after sinking in the conventional manner. The reduction in area is the significant strain in the tensile test, being equivalent to the reduction in mean diameter in tube-sinking. The significant strain of a sunk tube subjected to a tensile test is therefore the sum of the two strains referred to in the initial cross-sectional area.

Theoretical Analysis

The method of analysis used here assumes (*a*) that a pressure normal to the working tool-metal interface operates on the interface of tube and die, and that, neglecting the presence of the shear stress, this pressure is one of the principal stresses; (*b*) that because of friction, a shear stress operates at the interface; (*c*) that transverse sections are free of shear stresses; (*d*) that the normal stress acting on the transverse sections is uniformly distributed over the cross section and that it is another principal stress; (*e*) that the wall thickness of the tube is small in comparison to the tube diameter; and (*f*) that the wall thickness of the tube remains constant through the process. This last assumption is not strictly valid but has been found to be true within ±5 per cent (9, 10).

With these assumptions, two equations can be derived from Fig. 1, using the equilibrium of the forces in the longitudinal and radial directions. Summation of the longitudinal forces supplies one equation

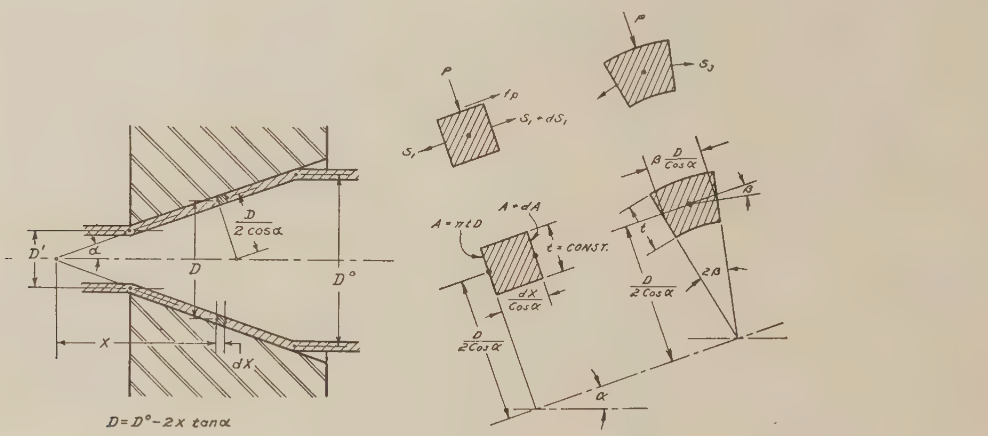

Fig. 1 Stresses in Tube-Sinking

$$\cos\alpha[(s_1 + ds_1)(A + dA) - s_1A] + p\sin\alpha\,\frac{dx}{\cos\alpha}\,\pi D + fp\cos\alpha\,\frac{dx}{\cos\alpha}\,\pi D$$

$$= \cos\alpha\, d(s_1A) + pdx\pi D\,(\tan\alpha + f) = 0 \ldots\ldots\ldots\ldots [1]$$

Using the geometrical relations, Fig. 1

$$D = 2x\tan\alpha \qquad dD = -2dx\tan\alpha \ldots\ldots\ldots\ldots [2]$$

$$A = \pi tD \quad dA = \pi tdD = 2\,\pi t\,dx\tan\alpha \ldots\ldots\ldots\ldots [3]$$

transforms Equation [1] to

$$\pi td(s_1D)\cos\alpha\,\pi DdD\,p\,\frac{\tan\alpha + f}{2\tan\alpha}$$

$$= \pi td(s_1D)\cos\alpha\,{}^1/_2\,\pi DdD\,pB = 0 \ldots\ldots\ldots\ldots [4]$$

where

$$B = \frac{\tan\alpha + f}{\tan\alpha} \ldots\ldots\ldots\ldots [5]$$

Summation of the radial components of forces yields

$$p2B\,\frac{D}{2\cos\alpha}\,\frac{dx}{\cos\alpha} + 2s_3Bt\,\frac{dx}{\cos\alpha} = 0$$

or

$$p = -s_3\,\frac{2t\cos\alpha}{D} \ldots\ldots\ldots\ldots [6]$$

Substituting Equation [6] into Equation [4] results in the general differential equation of tube-sinking

$$d(s_1D) = Bs_3dD \ldots\ldots\ldots\ldots [7]$$

Equation [7] is of the same form as that derived for rolling (3, 4, 5, 6, 7), wire-drawing (1, 2), or tube-drawing (8), the only difference being that the parameter B takes on different values for the various forming operations.

To relate the quantities s_1 and s_3 in Equation [7], some condition of plasticity must be invoked. The most accurate available is the strain-energy condition

$$(s_1 - s_2)^2 + (s_2 - s_3)^2 + (s_1 - s_3)^2 = 2k^2 \ldots\ldots\ldots [8]$$

where the quantities s_1, s_2, and s_3, are the three principal stresses in algebraically decreasing order of magnitude and k is the flow stress or yield strength of the metal as determined in simple tension or compression. However, the use of this condition involves considerable calculations. Under most general conditions Equation [8] sets certain limits on the values that $s_1 - s_3$ can assume, namely

$$k \leqq (s_1 - s_3) \leqq 1.15\,k \ldots\ldots\ldots\ldots [8a]$$

For the present case a constant average value may be taken as sufficiently accurate to represent the condition of plasticity throughout the sinking process, namely

$$s_1 - s_3 = 1.1\,k = k_0 \ldots\ldots\ldots\ldots [8b]$$

Substitution of Equation [8*b*] in Equation [7] and making the variable D dimensionless by multiplying the equation with D^o finally yields the linear differential equation

$$\frac{ds_1}{d(D/D^o)} + (1 - B)\frac{s_1}{D/D^o} = -B\frac{k_0}{D/D^o}$$

If the parameter B, is considered constant throughout the sinking process (i.e., if the die angle and coefficient of friction are constant) this equation may be integrated as follows

$$s_1 = -B\left(\frac{D}{D^o}\right)^{B-1}\int_1^o k_0\frac{d(D/D^o)}{(D/D^o)^B} + s_1^o\left(\frac{D}{D^o}\right)^{B-1} \quad \ldots\ldots [9]$$

where s_1^o is the stress for zero reduction, $D = D^o$.

The parameter B passes to unity as the coefficient of friction goes to zero. If the metal is further assumed to possess no strain-hardening (i.e., k_0 is constant) then Equation [9] becomes, neglecting s_1^o

$$s_1 = k_0 \log_e \frac{D^o}{D} \quad \ldots\ldots\ldots\ldots\ldots\ldots [9a]$$

This equation is commonly associated with ideal (i.e., frictionless) conditions, and has been deduced, for example, for wire-drawing, not only by using a method analogous to the present one (1, 2), but also by using stress-analysis methods based on the balance of the work consumed (11).

Another special case of the general Equation [9] is that in which friction exists but no work-hardening occurs. In this case k_0 is independent of D; and Equation [9] may be integrated to yield the following equation

$$s_1 = \frac{Bk_0}{B-1}\left[1 - \left(\frac{D}{D^o}\right)^{B-1}\right] + s_1^o\left(\frac{D}{D^o}\right)^{B-1} \quad \ldots\ldots [9b]$$

This equation yields the longitudinal stress at any position D, for a given D^o, and consequently also the sinking stress, $s_1 = s_1'$, at the exit, $D = D'$

$$s_1' = \frac{Bk_0}{B-1}\left[1 - \left(\frac{D'}{D^o}\right)^{B-1}\right] + s_1^o\left(\frac{D'}{D^o}\right)^{B-1} \quad \ldots [10]$$

Experimental Results

Hard Copper. The comparison of experimental data with the theory may be first made for hard copper. This material was selected for the investigation primarily because it represents a practical example of the conditions assumed to develop Equation [9b], namely, a material which does not strain-harden during the sinking process. In Fig. 2 the yield strength k, of the hard copper is shown as a function of the (mean) diameter change, after sinking through the 14-deg (half-angle) die. It will be noticed that an average value of k = 60,000 psi would describe the yield strength over the entire range of reduction, within ±3 per cent. A family of curves for the sinking stress s_1, obtained by substituting the value $k_0 = 1.1\ k$ = 66,000 psi, and a series of values for the parameter B, in Equation [9b] are also represented in Fig. 2.

The value of the integration constant C was determined experimentally by sinking a tube with the negligibly small reduction of 0.25 per cent, approximately; the measured value of 3000 psi agrees well with that extrapolated from the experimental sinking stresses for larger reductions.[4]

[4] Abundant experimental evidence may be found in the literature where a wire-drawing stress extrapolates to a definite positive stress value for zero reduction, see Thompson (12), Lueg and Pomp (13), Davis and Dokos (2). In discussing this positive value, Thompson describes it as "the extra pull required merely to overcome the frictional resistance in the die." Poeschl (14) and Davis and Dokos (2) attribute this positive value to a small transitional region of elasticity. Poeschl has attempted a mathematical analysis for this elastic region. In the present paper such positive values for soft copper or tube brass were found to be negligible whereas for hard copper they were found to be considerably higher, thus tending to confirm Poeschl's theory.

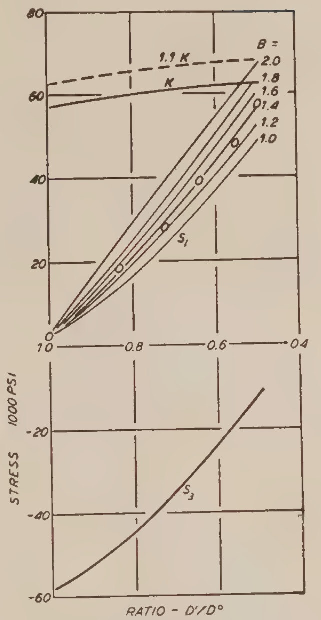

Fig. 2 Stress-Strain Diagram and Sinking-Stress Data for Hard Copper

(Experimental sinking-stress data for a 14-deg die half-angle have been entered as circular symbols.)

The experimental data agree rather closely with the theoretical curve for which the parameter B has a value of 1.4, approximately.

The hoop stress, $s_3 = s_1 - k_0$ Equation [8b] is also shown in Fig. 2, for a value of B = 1.4. The curve for the hoop stress represents its distribution over any length of contact, as its value is determined only by the local reduction of the considered cross section, irrespective of the total reduction of any particular draw.

Annealed Copper and Brass. For any soft material such as annealed copper and brass, the yield strength is primarily a function of the reduction. The stress-strain curves for these two metals derived from tensile tests are shown in Figs. 3 and 4.

The theoretical sinking stress can be obtained by graphical integration of Equation [9]. In Figs. 5 and 6, families of curves for the sinking stress, for a series of values for the parameter B, are given for soft copper and brass, respectively.

In comparing these theoretically derived curves with experimental data, it should be borne in mind that the stress-strain curve for a tube which had been sunk differs from that derived from a soft tube, as illustrated for one example in Fig. 7. This factor can be taken into account by a method employed by Sachs (15) for wire-drawing. From a comparison of the stress-strain curves in tension with those of sunk tubes as given in Fig. 7, a chart giving the effective reduction as a function of the actual reduction can be constructed.[5] Such a chart is shown in Fig. 8 for tubes sunk through the three different die angles included in this research. It will be noted that for large reductions the ideal and effective reductions become approximately equal. It is for this reason that this correction was not required for hard copper.

Figs. 9 to 13, inclusive, show the theoretical sinking stresses

[5] The difference between effective and actual reduction is attributed to the presence of shear stresses and shear strains. These have been demonstrated by means of grids on the cross section of wire, in both soft and hard copper, by Taylor and Quinney (16), and by Siebel (17).

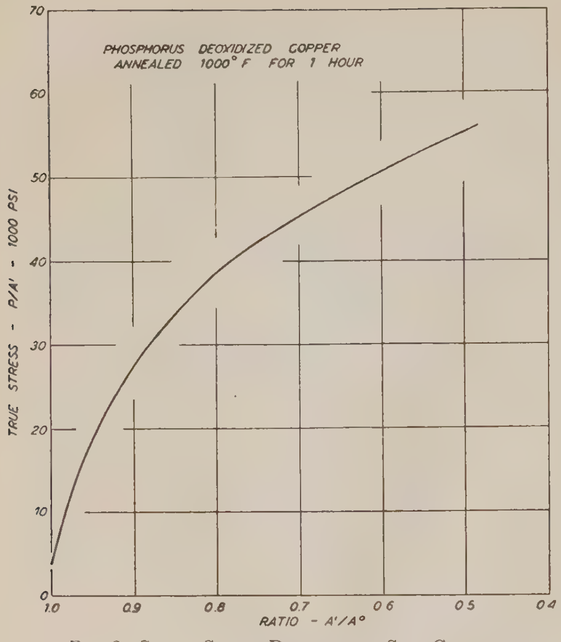

Fig. 3 Stress-Strain Diagram for Soft Copper

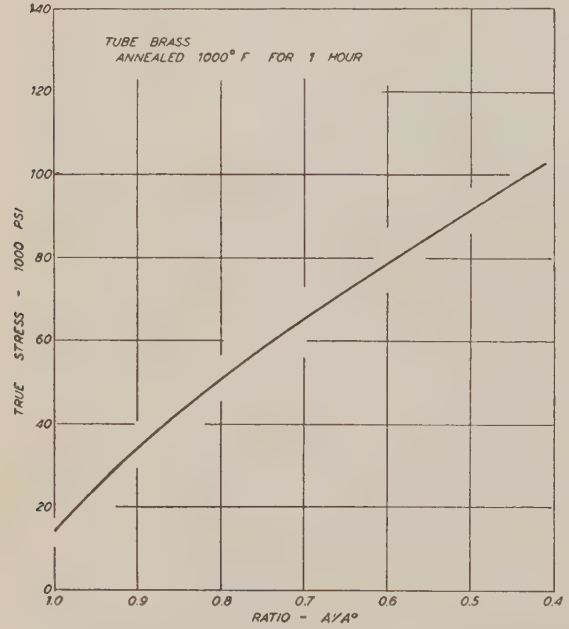

Fig. 4 Stress-Strain Diagram for Soft Brass

transformed by means of Fig. 8 from functions of the actual reductions, Figs. 5 and 6, into functions of the effective reductions. Each graph now applies only for a given alloy and a given die angle; and the range of parameter values B, represented in each graph covers the range of experimental scattering.

The experimental sinking stresses are shown in Figs. 9 to 13, inclusive, as open circles. It will be noticed that the scatter is greatest in the case of the 7-deg die and progressively lessens in

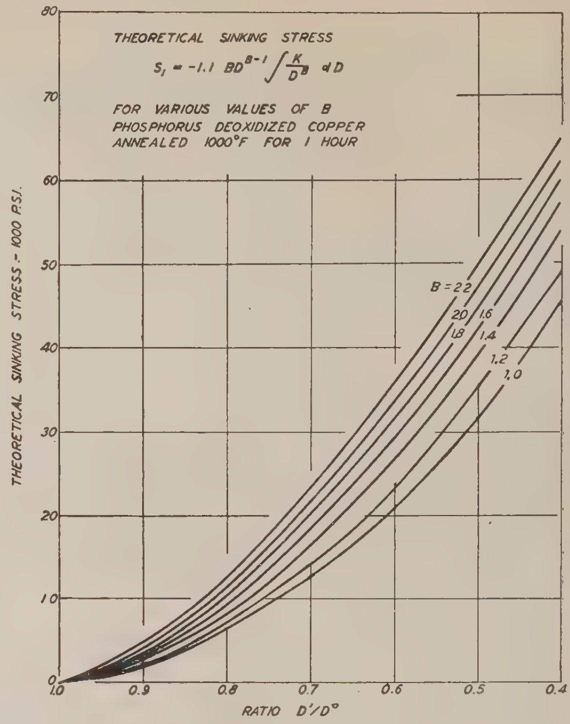

Fig. 5 Theoretical Sinking-Stress Curves for Soft Copper for Various Values of Parameter B

the case of the 14- and 27-deg die. These observations indicate that some variation in friction was encountered in the experiments.

In general, however, there is a fair agreement between the experimental value and a theoretical curve for a particular value of the parameter, B.

Coefficients of Friction. From the parameter B, and the die angle α, the frictional coefficient $f = \tan \rho$, can be readily determined by means of Equation [5]

$$\frac{\tan \alpha + f}{\tan \alpha} = B$$

In Fig 14 the parameter B is plotted as a function of the coefficient of friction, $\tan \rho$, for the three die angles, $\alpha = 7$, 14, and 27 deg employed in this investigation.

In Table 1 the parameters B are tabulated for the various metals and die angles investigated. The corresponding values of the coefficient of friction, f, are also included in Table 1.

TABLE 1 PARAMETERS, DIE ANGLES, AND COEFFICIENTS OF FRICTION OF METALS INVESTIGATED

Material	Die angle, deg	Parameter, B	Coefficient of friction, f
Hard copper.........	14	1.4	0.10
Soft copper..........	14	1.4	0.10
	27	1.3	0.15
Tube brass...........	7	2.6	0.20
	14	1.5	0.13
	27	1.3	0.15

These coefficients of friction are for both the 14- and 27-deg die of the same order of magnitude as those obtained by other investigators for wire-drawing (1, 2). However, for the 7-deg die, which was not as finely polished as the 14- or 27-deg die, the friction was found to be approximately twice as great.

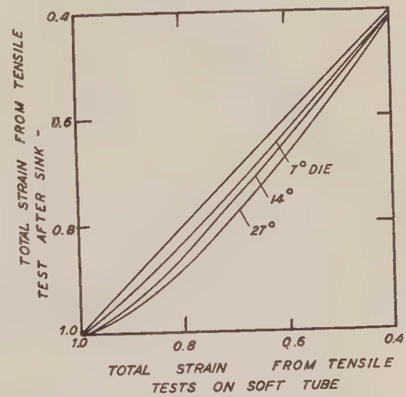

FIG. 8 CHART CORRELATING REDUCTION IN AREA FOR GIVEN STRESS ON STRESS-STRAIN DIAGRAMS OF SOFT TUBES AND SUNK TUBES

CONCLUSIONS

Any theory of a metal-forming process involves a number of simplifying assumptions in order to obtain sufficiently simple equations to allow numerical or graphical evaluation. Some discrepancies between theory and experimentation may therefore be expected. The analysis of tube-sinking presented here contains some minor refinements as compared with previous analyses of related processes in that no mathematical approximations are used other than that employed for the condition of plasticity. The experimentation indicates that this has yielded the gratifying result that the sinking stresses (i.e., the draw forces and the power consumption, excluding the losses in the equipment) can be calculated satisfactorily to within ± 2000 psi for soft copper drawn with a 27-deg die, and to within ± 9000 psi for soft tube brass drawn with a 7-deg die. This range of agreement is comparable to that reported in studies on wire-drawing, tube-drawing, etc.

It must be emphasized, however, that such an agreement cannot be claimed for either the distributions of the stresses or the strains over the cross section in drawing processes. So far, no theoretical analysis is available which promises to yield accurate results regarding the stress and strain distributions. This knowledge would be very desirable as the stress distribution is important in respect to various commercial problems, particularly those involving residual stresses.

Appendix

COMPARISON OF TUBE-SINKING WITH WIRE-DRAWING; EFFECTS OF TUBE THICKNESS

The experimental data on tube-sinking were obtained with thin-walled tubes, their ratio of wall thickness to diameter (relative thickness) being between $t_0/D^o = 0.01$ to 0.05. Tubes having a larger relative thickness were not investigated.

However, some indication regarding the effect of relative thickness can be obtained by comparing the stresses required to draw, respectively, thin-walled tube with those required to draw wire (or rod), other conditions (metal, dies, lubricant) being identical.

The wire represents the limiting condition of a tube, the relative wall thickness being $t_0/D^o = 0.5$. The wire-draw stress is given, according to Sachs (1) by the equation

$$s_1'' = \frac{B_1 k}{B_1 - 1}\left[1 - \left(\frac{D'}{D^o}\right)^{2(B_1-1)}\right] \qquad [11]$$

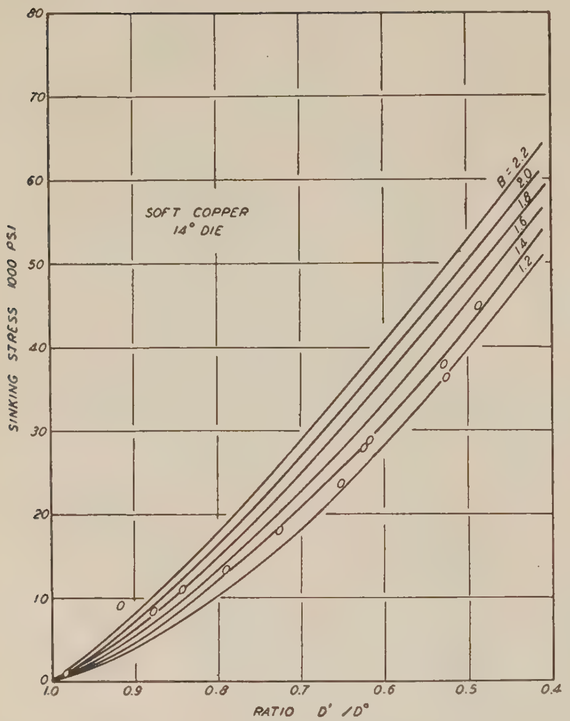

FIG. 9 THEORETICAL SINKING-STRESS CURVES CORRECTED FOR DIFFERENCES IN STRESS-STRAIN DIAGRAMS SHOWN IN FIG. 7

(Curves are for soft copper sunk through a 14-deg die. Experimental data are represented as circles.)

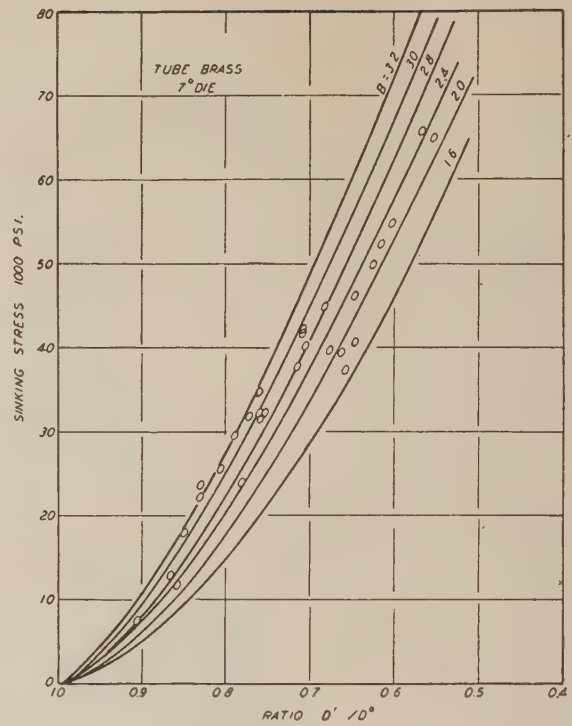

FIG. 11 THEORETICAL SINKING-STRESS CURVES CORRECTED FOR DIFFERENCES IN STRESS-STRAIN DIAGRAMS SHOWN IN FIG. 7

(Curves are for soft tube brass sunk through a 7-deg die. Experimental data are represented as circles.)

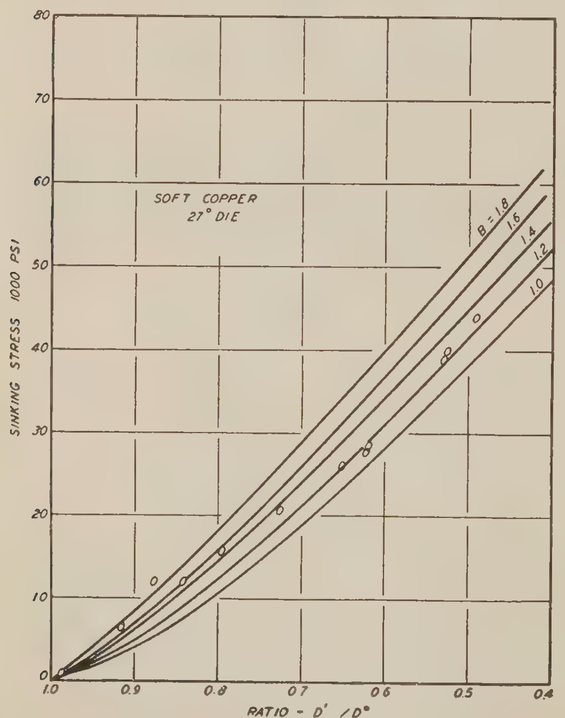

FIG. 10 THEORETICAL SINKING-STRESS CURVES CORRECTED FOR DIFFERENCES IN STRESS-STRAIN DIAGRAMS SHOWN IN FIG. 7

(Curves are for soft copper sunk through a 27-deg die. Experimental data are represented as circles.)

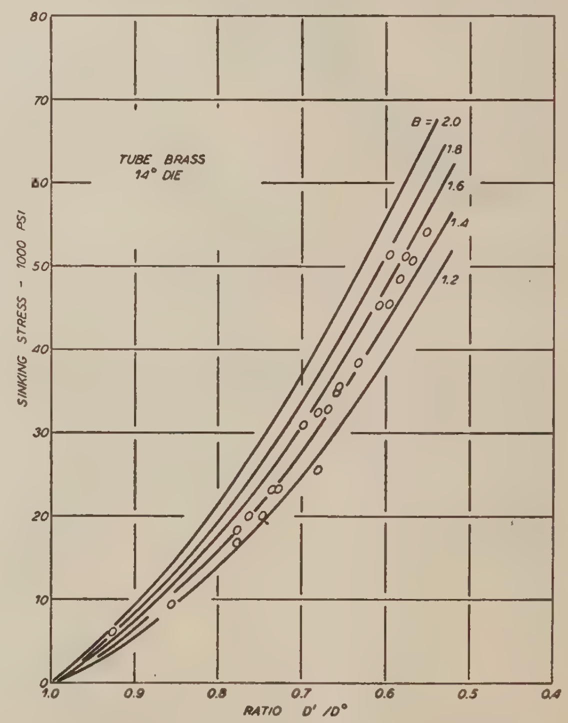

FIG. 12 THEORETICAL SINKING-STRESS CURVES CORRECTED FOR DIFFERENCES IN STRESS-STRAIN DIAGRAMS SHOWN IN FIG. 7

(Curves are soft tube brass sunk through a 14-deg die. Experimental data are represented as circles.)

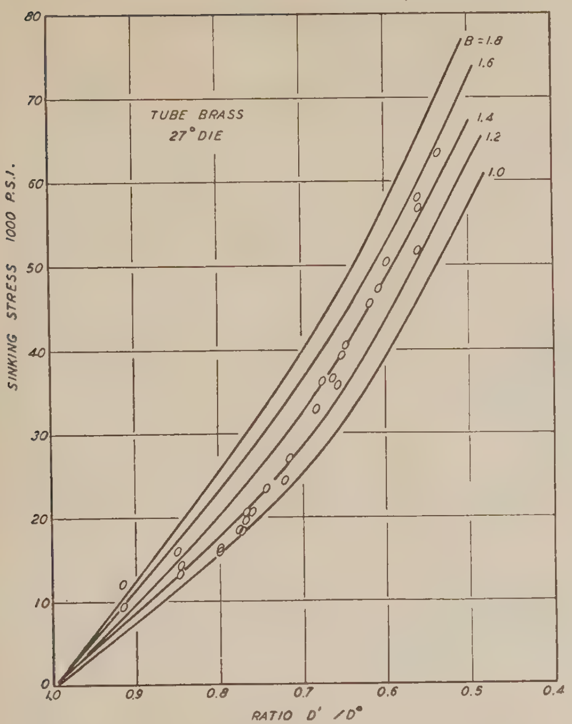

FIG. 13 THEORETICAL SINKING-STRESS CURVES CORRECTED FOR DIFFERENCES IN STRESS-STRAIN DIAGRAMS SHOWN IN FIG. 7
(Curves are for soft tube brass sunk through a 27-deg die. Experimental data are represented as circles.)

Neglecting the back pull s_1^o, the sinking stress given by Equation [10] becomes

$$s_1' = \frac{Bk_0}{B-1}\left[1-\left(\frac{D'}{D^o}\right)^{B-1}\right] \quad \text{[10a]}$$

The parameters, B_1 and B, in Equations [11] and [10a] are identical (see Equation [5])

$$B_1 = B = \frac{\tan \alpha + f}{\tan \alpha}$$

Considering that the cross-sectional area in wire-drawing is

$$A_1 = \pi D^2$$

consequently

$$\frac{A_1'}{A_1^o} = \left(\frac{D'}{D^o}\right)^2 \quad \text{[12]}$$

On the other hand, the cross-sectional area in tube-sinking is

$$A = \pi t D$$

consequently

$$\frac{A'}{A^o} = \frac{D'}{D^o} \quad \text{[13]}$$

Introducing Equations [12] and [13] into Equations [11] and [10a], respectively, yield the following

For wire-drawing

$$s_1'' = \frac{Bk}{B-1}\left[1-\left(\frac{A_1'}{A_1^o}\right)^{B-1}\right] \quad \text{[11a]}$$

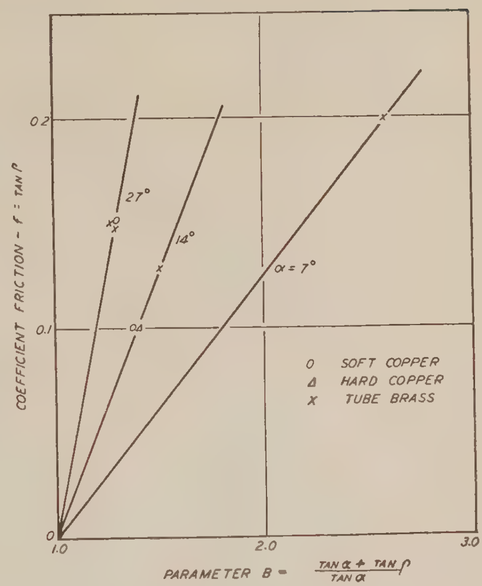

FIG. 14 PARAMETER B AS A FUNCTION OF COEFFICIENT OF FRICTION AND DIE ANGLE

and for tube sinking

$$s_1' = \frac{Bk_0}{B-1}\left[1-\left(\frac{A'}{A_1}\right)^{B-1}\right] \quad \text{[12a]}$$

Thus for a given ratio of cross sections at the entrance and exit, the ratio of the draw stresses for wire-drawing and tube-sinking should be

$$\frac{s_1''}{s_1'} = \frac{k}{k_0} = \frac{k}{1.1\,k} = 0.91$$

So far, the comparison of the two processes has not considered the effects of the shear stresses at the interface between die and metal, which increase the yield strength over that of a homogeneously deformed metal, as discussed previously. If these effects are larger in tube-sinking than in wire-drawing, the ratio k/k_0 would be larger than 0.9, and vice-versa.

To test these conceptions, two series of tests with a 14-deg and a 27-deg (half-angle) die, respectively, were carried out on annealed copper. The processing of both the copper tubes and the copper wire was such that identical stress-strain curves were obtained, represented in Fig. 3. All test conditions were also the same, as described previously for tube-sinking.

The results of the experimentation are shown in Figs. 15 and 16. For the smaller die angle, 14-deg, the ratio of the draw stresses for wire-drawing and tube-sinking respectively, is possibly slightly larger than 0.9. For the larger die angle this ratio is rather close to unity. Considering that the effects of shear increase with increasing die angle, the following conclusions can be drawn from these tests: (a) The draw stresses in tube-sinking and wire-drawing, respectively, correspond approximately to the fundamental difference in the flow stress derived from the difference in their stress states; (b) the shear stresses occurring under commercial processing conditions affect the metal flow in wire-drawing to a (slightly) greater extent than in sinking a thin-walled tube.

FOREWORD

Both alphabetical and geographical lists of members of all grades except Student Members are included in this issue of the Membership List of The American Society of Mechanical Engineers. It is published as a Section Two of the A.S.M.E. Transactions, the third Section Two of Transactions in 1946. The Indexes to Publications appeared in January and the personnel of Council and committees and other general information in February. The colored page in the front of the Membership List is a guide to the latter pamphlet and to other sources of information about the Society.

Alphabetical List

Each entry in the Alphabetical List covers the member's grade and year of membership, symbols indicating registration in Professional Divisions, Society office held or award received, and his address.

The dates and letter symbols in parentheses immediately following the name of a member indicate his grade of membership and year of election or promotion to each grade. Where a single date is not accompanied by a letter symbol, the grade of Member is to be understood. Also where several dates are given, with no letter symbols, the final date indicates the year of election to full membership. The key to the symbols appears on the following page.

Professional Divisions Registration

One or more letter symbols appearing in a second parenthetical group designate Professional Divisions of the Society in which the member has signified his interest. The card sent to members asking for information for the 1946 Membership List gave them the opportunity to register in as many as six divisions, in order of interest. If a member failed to bring his Professional Division registration up to date, his latest previous registration has been retained. In cases where no preferred order has been indicated, the symbols are given in alphabetical order. The key to the symbols is given on the next page.

Addresses

The addresses given are, in most cases, those on record on March 1, 1946, the date set for the return of the information cards sent to members. However, the publication of the Membership List having been delayed, late returns were incorporated as long as was possible without causing further delay and an excessive increase in publication costs. Special attention was given to the listings of members being released from the armed forces, but up-to-date information regarding such members has not been received in many cases.

The extension of the actual closing date also made it possible to include all those who were in good standing on April 1, 1946.

Geographical List

The Geographical List gives the names of those in each locality. Facing the first page of that section of the book is an index giving the number of the page on which each country will be found.

In the United States and Canada, the name of each city which falls within a Section is followed by the name of that Section. Members residing in cities where no Section is mentioned may affiliate with any Section, without additional dues, upon request to the headquarters of the Society. Members are grouped according to the business addresses unless otherwise requested. Members of the armed forces who furnished an address in the United States in addition to an A. P. O. or F. P. O. service address, are listed under the former.

Restrictions on Use of Membership List

This Membership List is issued for the personal use of members of The American Society of Mechanical Engineers in connection with Society and professional affairs. Each member is expected to conserve it and not to permit his copy to be used for the basis of circularization. Such use is annoying to fellow members.

Key to Symbols

Grades of Membership

H—Honorary
F—Fellow
A—Associate
J—Junior

Professional Divisions

A—Aviation
B—Applied Mechanics
C—Management
D—Materials Handling
E—Oil & Gas Power
F—Fuels
G—Graphic Arts
H—Hydraulic
J—Metals Engineering
K—Heat Transfer
L—Process Industries
M—Production Engineering
N—Machine Design Group
O—Consulting Engineering Group
R—Railroad
S—Power
T—Textile
W—Wood Industries

Z—Industrial Instruments

ALPHABETICAL LIST OF MEMBERS

A

Aarflot, Martin G. ('31) (BHK), Checker (Engrg.), Gibbs & Cox, Inc., 21 West St., New York, N.Y.; *for mail,* 180 N. 17th St., East Orange, N.J.

Aaron, Charles (J'37) (NOMB), Mch. Design Engr., Algren Mfg. Co., 325 Lafayette St., New York; *for mail,* 50 Westminster Rd., Brooklyn 18, N.Y.

Aaron, Hart Richard ('22; '26; '35) (CY), Lt. Comdr., U.S.N., 45 Rico Way (Marina Dist.), San Francisco 23, Calif.

Aaron, Robert Hart ('35; '45) (NMBJA), Design Engr., Harvey Mch. Co., 6200 Avalon Blvd., Los Angeles 3; *for mail,* 4186 Garthwaite Ave., Los Angeles 43, Calif.

Abadjieff, Ivan V. (J'29) (CHKFYM), Devel. & Pat. Engr., Leland-Gifford Co., 1001 Southbridge St.; *for mail,* Box 293, Worcester 1, Mass.

Abaya, Gonzalo T. (J'38) (CEM), 198 Espana St., Manila, P.I.

Abbey, Harold George (J'34) (ELZCS), Pres., Gen. Mgr., Ch. Engr., Indus. Installations Corp., 210 E. 40th St., New York 16, N.Y.

Abbondante, Cosmo (J'45) (MNCDBA), Tool Designer, Mech. Engr., Waltham Watch Co., 221 Crescent St., Waltham; *for mail,* 31 Rose St., Somerville 43, Mass.

Abbott, Douglas T. (J'42) (HCJMBA), Ch. Engr., Columbian Bronze Corp.; *for mail,* 188 Mt. Joy Ave., Freeport, N.Y.

Abbott, Ernest James ('37) (BCMNZ), Pres., Gen. Mgr., Physicists Research Co., 321 S. Main St., Ann Arbor, Mich.

Abbott, Horace Porter (J'42) (CLM), Supt., Lever Bros. Co., 5300 Holabird Ave., Baltimore 24; *for mail,* 4810 Keswick Rd., Baltimore 10, Md.

Abbott, James, Jr. (J'21), Mem. Tech. Staff, Bell Tel. Labs., Inc., New York, N.Y.; *for mail,* 334 Clinton Pl., Hackensack, N.J.

Abbott, Richard LeMoine (J'39) (SKMFJ), Sr. Mar. Draftsman, Fed. Shipbldg. & Dry Dock Co., Lincoln Highway, Kearny; *for mail,* 49c Garwood Trail, Lake Arrowhead, Denville, N.J.

Abbott, Ward D. (J'41) (MCSK), 33 Chauncy Lane, Orchard Park, N.Y.

Abbott, William George, Jr. ('19; '35) (TEALYN), Treas., Hillsborough Mills, Box 154, Wilton, N.H.

Abbott, William L. ('91; F'36; H'40) (BFS), *Manager,* '07-'10, *President,* '26; Treas., Pal-Verd, Inc.; *for mail,* 3500 Lake Shore Dr., Chicago, Ill.

Abderhalden, Robert Bruce (J'45), Design Engr., Westinghouse Elec. Corp., Wapak Rd.; *for mail,* 724 N. West St., Lima, Ohio.

Abdun-Nur, Edward Amin ('24; '39) (BHR), Engr., U.S. Bur. of Reclamation, Custom House, Denver 2, Colo.

Abel, Arthur William, Jr. (J'40) (ESA), Sales Engr., Cooper-Bessemer Corp., Box 1928, Odessa, Tex.

Abel, Stephen Taylor ('38) (MC), Ch. Engr., Engrg. Div., W. L. Coston & Sons, 1803 1st Natl. Bank Bldg., Birmingham 3; *for mail,* 3620—13th Ave. N., Birmingham 4, Ala.

Abel, Walter Lewis (J'41), Asst. Research Dept. Head, Research Div., United Shoe Mchy. Corp., Balch St., Beverly, Mass.

Abell, John Daniel (J'45) (CDJMN), Mech. Engr., Plant Maint., Internatl. Harvester Co. of Can., Ltd.; *for mail,* Apt. 1, 85 Proctor Blvd., Hamilton, Ont., Can.

Abelson, Richard Dodge (J'45) (CMO), Asst. Ch. Indus. Engr., Maremont Auto. Products Inc., 1625 S. Ashland Ave., Chicago 8; *for mail,* 5138 University Ave., Chicago 15, Ill.

Abendschein, Edward John (J'35) (CMNJ), Gen. Mgr., Chisholm-Ryder Co. of Pa., Hanover, Pa.

Aber, Joseph Stewart (J'43) (BHNSYZ), Mech. Engr., Goodall Rubber Co., 5 S. 36th St., Philadelphia; *for mail,* 1703 S. 58th St., Philadelphia 43, Pa.

Abercrombie, James H. ('01), Retired; "Rutland," West St., Reigate, Surrey, England.

Abercrombie, W. Taylor, Jr. ('21; '25; '35) (CHKMN), Sales Engr., U.S. Pipe & Fdy. Co., Burlington; *for mail,* Branch Pike, R.F.D. 2, Riverton, N.J.

Abernathy, George T. ('41) (HCS), Hyd. Engr., Newport News Shipbldg. & Dry Dock Co., Newport News; *for mail,* 126 James River Dr., Hilton Village, Va.

Aborn, Robert H. ('37) (JB), Supvr., Phys. Metal. Research, U.S. Steel Corp., Lincoln Highway, Kearny, N.J.

Abrahm, Michael Charles ('41) (KSE), Prin. Mech. Engr., New Orleans Pub. Serv., Inc., 317 Baronne St., New Orleans 9, La.

Abrams, Arnold (J'38), Project Dir., Jordanoff Aviation Corp., 595 Madison Ave.; *for mail,* 70 W. 95th St., New York, N.Y.

Acheson, Howard A. ('24; '34) (AFGY), Pres., Acheson Colloids Corp., Washington Ave., Port Huron, Mich.

Acheson, Louis Kruzan ('44) (CHBZTY), Lab. Co-ordinator, Hoover Co.; *for mail,* 816 Portage St., North Canton, Ohio.

Achilich, John Henry (J'42) (MAEHJY), Tool Engr., Plant 5, Grumman Aircraft Engrg. Corp., Bethpage, N.Y.

Ackart, Everett G. ('17), Ch. Engr., E. I. du Pont de Nemours & Co., Wilmington, Del.

Acker, Alvin Wayne (J'42) (KAEHB), Army Air Forces, 1106th Base Unit, A.P.O. 845, c/o Postmaster, Miami, Fla.

Acker, George H. ('22; '28; '35) (BMN), V.P., Engrg. & Prod., Cleveland Worm & Gear Co., 3249 E. 80th St., Cleveland 4, Ohio.

Acker, Sidney H. ('35) (ERS), Mech. Engrg. Hall, Vanderbilt Univ., Nashville, Tenn.

Ackerman, Donald E. ('44) (CMDJLW), Mgmt. Consultant, McKinsey & Co., 240 Montgomery St., San Francisco 4, Calif.

Ackerman, George Ernest ('44), Cons. Engr., Mem. of Partnership, Holland, Ackerman & Holland, 20 N. Wacker Dr., Chicago; *for mail,* 1017 Wenonah Ave., Oak Park, Ill.

Ackerman, Robert Allen (J'44), 404 Yale Ave., Morton, Pa.

Ackerman, William Louis ('34; '46) (JMS), Mch. Designer, Keystone Steel & Wire Co., Peoria; *for mail,* 202 Carrie Ave., Peoria 5, Ill.

Ackermann, Frederick Andrew (J'39) (ABJMN), Designer, Van Tuyl Associates, 30 N. La Salle St., Chicago; *for mail,* 3107 S. Ridgeland Ave., Berwyn, Ill.

Ackert, George Ford (J'38) (BEM), Mech. Engr., Constr. Mgmt., Inc., 27 William St., New York; *for mail,* 29-16—166th St., Flushing, N.Y.

Ackley, Robt. A. ('40) (BLS), Design Engr., Republic Flow Meters Co., 2240 Diversey Pkwy., Chicago; *for mail,* 1535 Forest Ave., Wilmette, Ill.

Acomb, William Edward (J'39) (HWFSMC), Engr., Northwestern Mutual Fire Assn., 217 Pine St., Seattle 1; *for mail,* 3711 Tilden St., Seattle 99, Wash.

Acosta, Allan James (J'45) (HNMEJF), Ensign, U.S.N.R., U.S.S. *Rockingham,* APA-229, F.P.O., San Francisco; *for mail,* 1509 Artesia Blvd., Long Beach 5, Calif.

Acres, Harold Didsbury (J'43) (BYHASM), R.R. 1, Britannia Bay, Ont., Can.

Acurso, Louis A. (J'39), Asst. Engr., Pacific Gear Works, 2053 E. 38th St., Huntington Park, Calif.

Adair, John Gillis ('22; '30) (RSBEF), Mech. Engr., Interstate Commerce Comm., Washington 25, D.C.

Adams, Arlington Richard (J'39) (ABENS), Mech. Engr., Aircraft Eng. Research Lab., Natl. Advis. Com. for Aero., Cleveland Airport, Cleveland; *for mail,* 2181 Atkins Ave., Lakewood 7, Ohio.

Adams, Arthur Stanton ('41) (BACE), Office of Provost, Cornell Univ., Ithaca, N.Y.

Adams, Campbell V. ('19; '35), Mech. Engr., Asst. to Gen. Mgr., Vulcan Iron Works, 327 N. Irving Ave.; *for mail,* 2934 Wilson Ave., Chicago, Ill.

Adams, Charles Edward, Jr. (J'46), 318 Spring St., Portland, Me.

Adams, Clarence Harrison ('38) (BJ), Mech. Engr., Cone Automatic Mch. Co., Inc.; *for mail,* 29 N. Main St., Windsor, Vt.

Adams, Clarence Smith ('16; '25) (JLFDSM), Mech. Engr., Federated Metals Div., Am. Smelting & Refining Co.; *for mail,* 1820 Davis Ave., Whiting, Ind.

Adams, Comfort Avery ('17; F'39) (BEJKOR), Cons. Engr., Edward G. Budd Mfg. Co., 2450 Hunting Pk. Ave., Philadelphia 32, Pa.

Adams, Conrad Robert ('14; '35) (BCMNA), Pres., Gen. Mgr., Adams Engrg. Die & Tool Co., 1702 W. Washington St., South Bend 21, Ind.

Adams, E. Eugene ('35) (BGR), V.P., Trans. Research, Pullman Co., 79 E. Adams St., Chicago, Ill.

Adams, Earl Eugene ('44) (ECOY), Engr., C. L. Thompson & Co., 21 E. 40th St., New York 16; *for mail,* 969 Park Ave., New York 28, N.Y.

Adams, Franklin S. ('24; '33), Box 512, Stockbridge, Mass.

Adams, Frederick Clarke (J'45) (CMY), 67 Constance St., Toronto 3, Ont., Can.

Adams, Harold Eugene ('30) (HNEASO), Ch. Engr., Nash Engrg. Co., South Norwalk, Conn.

Adams, Harold Lamont ('30; '40) (AB), *Student Award,* '30; Unit Ch., Struc. Testing, Boeing Aircraft Co., 200 W. Michigan St., Seattle 6; *for mail,* 3222 Sierra Dr., Seattle 44, Wash.

Adams, Henry R. ('38), Treas., Gen. Mgr., William Bergfels & Co., Inc., 40 Walnut St., Newark; *for mail,* 53 Woodland Rd., Madison, N.J.

Adams, James Francis, Jr. (J'45) (OJKLSM), Engr., Tech. Serv., Solvay Process Co., 523 Allen St., Syracuse, N.Y.

Adams, James Walter ('44) (CELM), Adams Engrg. Co., 1618 N. Fitzhugh, Dallas 4; *for mail,* 3525 Milton Ave., Dallas 5, Tex.

Adams, John ('36; '45) (BCJLMO), Ch. Tool Designer, Detroit Gear & Mch. Co. (Div. of Borg-Warner Corp.), 670 E. Woodbridge, Detroit; *for mail,* 2031 Carpenter St., Detroit 12, Mich.

Adams, John James (J'44), Cpl., Army Serv. Forces, 3rd Platoon, 3189th Engr. Serv. Bn., Trng. Center, Ft. Lewis, Wash.

Adams, Lyman Daniel ('17; '24) (ABCM), V.P., Gen. Mgr., Barnes-Gibson-Raymond (Div. of Associated Spring Corp.), Miller Ave., Detroit 11, Mich.

Adams, Orlando Percival ('22; '31) (JSAHFC), Dir. of Devel., Natl. Tube Co., Frick Bldg., Pittsburgh 30, Pa.

Adams, Orville L., Sr. (A'43) (CEL), Editor, Tech. Indus. Dept., Prentice-Hall, Inc., 70—5th Ave.; *for mail,* 32 W. 40th St., New York, N.Y.

Adams, Paul ('42) (BCDHY), Supvr., Design & Drafting, Hood Rubber Co., 98 Nichols Ave., Watertown, Mass.

Adams, Raleigh John ('28; '35) (BJS), 644 Diversey Pkwy., Chicago, Ill.

Adams, Richard Donald ('37; '46) (EKSY), Pres., R. D. Adams Co., 555 Post St., San Francisco 2, Calif.

Adams, Robert Powell (J'40) (HBM), c/o Y.M.C.A., DeKalb & Airy Sts., Norristown, Pa.

Adams, Stafford Morley Sidney (J'31) (CNMDHY), Works Mgr., Truscon Steel Co. of Can., Ltd., 2275 Ottawa St., Walkerville; *for mail,* 2241 Moy St., Windsor, Ont., Can.

Adams, Thomas Burton, Jr. (J'42) (AJM), 1636 Maine St., Quincy, Ill.

Brown, William John ('35; '45), Pres., Techni-finish Lab., Inc., 38 Scio St., Rochester 3, N.Y.
Brown, William Wilson ('44) (SKHOE), Engr., Constr. Engrg. Div., Detroit Edison Co., 2000—2nd Ave., Detroit; *for mail*, 11380 Nottingham, Detroit 24, Mich.
Brownback, Henry L. ('21; '30), Cons. Engr., 823 W. Main St., Norristown, Pa.
Browne, Albert Alexander ('45) (CJMNYZ), Mgr. Engrg. & Sales, Joshua Hendy Iron Works, Sunnyvale; *for mail*, 1755 University Ave., Palo Alto, Calif.
Browne, Andrew T. ('28; '34; '35) (BERY), ACF-Brill Motors Co., 62nd St. & Woodland Ave., Philadelphia 42, Pa.
Browne, Bard ('20; '35) (BEKRS), V.P., Sales, Superheater Co., 60 E. 42nd St., New York 17; *for mail*, Braeside Lane, Dobbs Ferry, N.Y.
Browne, Edmund Victor (J'43) (NCJMBZ), Mch. Designer, M. L. Baylard & Co., 20th & Indiana, Philadelphia; *for mail*, 338 Fairmont Ave., Philadelphia 23, Pa.
Browne, Frank A. ('13), 215 S. Aberdeen Ave., Wayne, Pa.
Browne, Kenneth Alan ('45) (RFEAB), Research Consultant, Pres.'s Office, Chesapeake & Ohio Ry. Co., 3305 Terminal Tower, Cleveland 1, Ohio.
Browne, Leland Warren ('32; '35) (CLJ), V.P., Darby Corp., 1st & Walker Sts., Kansas City 15, Kan.
Browne, William Hooper (J'36) (EFNBRS), Research Engr., Battelle Memorial Inst., 505 King Ave., Columbus 1, Ohio.
Brownell, Clifford Eaton (J'45) (DNBHKL), Ch. Engr., Savory, Inc., 90 Alabama St., Buffalo 4, N.Y.
Browning, Frank H. ('14) (CES), Engr. Examiner, Seattle Civ. Serv. Comm., 605 County City Bldg.; *for mail*, 1514—35th Ave., Seattle, Wash.
Browning, Winston Headly (J'42) (LKBFJH), Sr. Inspr., Shell Oil Co., Box 262, Wood River; *for mail*, 502 Reller Ave., Roxana, Ill.
Brownlie, David ('21) (SWYFEZ), Cons. Engr., 56 Grange Rd., Ealing, London W 5, England.
Brownlie, William Neilson ('42) (CEHORS), Mutual Boiler Ins. Co. of Boston, 60 Batterymarch St., Boston, Mass.
Brownscombe, Philip Joslyn ('36; '45) (NBM), 19 N. Hillside Ave., Chatham, N.J.
Brownstein, Benjamin ('22) (ABEFHL), Mech. Engr., Jones & Laughlin Steel Corp., Aliquippa; *for mail*, 517—4th St., Ellwood City, Pa.
Bruback, Theodore McLane ('41) (BH), Appropriation Control Engr., Gary Sheet & Tin Mill, Carnegie-Ill. Steel Corp.; *for mail*, 578 Broadway, Gary, Ind.
Bruce, Albert White (J'36) (EFKS), Asst. Engr., Div. of Steam Engrg., Pacific Gas & Elec. Co., 245 Market St., San Francisco 5; *for mail*, 3734 Broderick St., San Francisco 23, Calif.
Bruce, Alexander Douglas (A'45), Pres., Vapor Car Heating Co., Inc., 80 E. Jackson Blvd., Chicago 4; *for mail*, 1319 Ridge Ave., Evanston, Ill.
Bruce, Alfred W. ('43) (ERS), 242 E. 19th St., New York, N.Y.
Bruce, Archibald K. ('27) (ERS), Sr. Partner, Robert Bruce & Sons, Moorgate Hall, Moorgate, London, England.
Bruce, Cecil Douglas ('43) (HKMN), Mech. Engr., Am. Cast Iron Pipe Co., 2930 N. 16th St., Birmingham 4, Ala.
Bruce, Irving Whiton (J'45) (JMN), Engr., Head of Engrg. Dept., Pacific Gear & Tool Works, 1035 Folsom St., San Francisco 3; *for mail*, 926 Evelyn Ave., Albany 6, Calif.
Bruce, Norman Clement (J'43), Foreman, Cutting Tools Div., Neon Products of West. Can., Ltd., 260 Terminal Ave.; *for mail*, 4474 W. 5th Ave., Vancouver, B.C., Can.

Bruce, Victor Gardiner (J'42) (BNAG), Graduate Student, Stanford Univ., Box 909, Stanford Univ., Calif.
Bruce, William (J'41) (EFSK), Instr. Mech. Engrg., Univ. of Toronto, Toronto; *for mail,* 16 Graham Gardens, Toronto 10, Ont., Can.
Bruce, William Lee (J'42) (EHS), Engr's. Asst., Allis-Chalmers Mfg. Co., Milwaukee 1; *for mail,* 1563 S. 82nd St., West Allis 14, Wis.
Bruck, Albert George ('20; '35) (MCJB), Works Mgr., King Mch. Tool Co., Clifton & B. & O. R.R., Cincinnati; *for mail,* 1529 Wittlou Ave., Cincinnati 24, Ohio.
Brucker, Lyle A. (J'41), 930 E. Russell Ave., Flint 5, Mich.
Bruckmann, Hugo C. ('27; '35) (DMW), Auchentorlie House, Seedhill Rd., Paisley, Scotland.
Bruckner, Robert Earll ('25; '41) (RENSKJ), Cons. Engr., Cons. Tech. Editor, *Produce Engineering,* McGraw-Hill Publ. Co., Inc., 330 W. 42nd St., New York, N.Y.; *for mail,* Box 45, Upper Montclair, N.J.
Brueggeman, Karl O. (J'40) (R), Sgt., Co. B, 721st Ry. Opera. Bn., A.P.O. 465, New York, N.Y.; *for mail,* 1945 Kearney, Denver 7, Colo.
Bruehl, Lawrence ('30; '35) (BHKNSM), Mech. Engr., Internatl. Business Mchs. Corp., 310—5th Ave., New York 1; *for mail,* 509 E. 77th St., New York 21, N.Y.
Brugler, Maynard Wesley ('36; '44) (CAYR), Field Engr., Timken Roller Bearing Co., 16 W. 60th St., New York 23, N.Y.
Bruhn, Neils (J'24), Elec. Tester, Brooklyn-Manhattan Transit Co., 500 Kent Ave., Brooklyn; *for mail,* 362 Oak Ave., Cedarhurst, L.I., N.Y.
Bruister, Thomas James (J'41) (BJMN), Mech. Engr., Designer, Naval Research Lab., Rm. 206, Bldg. 1, Washington 20, D.C.; *for mail,* 4124 N. 3rd Rd., Arlington, Va.
Brukardt, Arthur Major (J'43) (MACE), 2nd Lt., QM. Corps, U.S.A., 83rd Co., Army Serv. Forces Trng. Center, Camp Lee, Va.
Brumbaugh, C. C. ('41) (CLDKS), Dir. of Engrg., Diamond Alkali Co.; *for mail,* R.F.D. 3, Painesville, Ohio.
Brummerstedt, Egon Fritjoph (J'43) (BDJL), Ch. Estimator, Foster Wheeler Corp., 165 Broadway, New York 6, N.Y.
Brune, Carleton Edward ('22; '27; '35) (SKHFJB), Engr., Am. Gas & Elec. Serv. Corp., 30 Church St., New York 8, N.Y.; *for mail,* 93 Highland Ave., Metuchen, N.J.
Brunelle, Henry Eugene, Jr. (J'38) (ABMNRE), Devel. Engr., Gen. Elec. Co., 1 River Rd., Schenectady 5; *for mail,* 1317 Regal Ave., Schenectady 8, N.Y.
Brunett, Adrian L. ('19; '25) (BMS), Mech. Engr., Fed. Works Agency, Pub. Bldgs. Admin., Repair Sec., Procurement Bldg., 7th & D Sts., S.W., Washington, D.C.; *for mail,* Box 36, Rockville, Md.
Bruney, Robert Charles (J'41) (AMJNYZ), Engrg. & Equip. Inspr. (Ord.), U.S. Naval Ord. Plant, 21st & Arlington, Indianapolis 6; *for mail,* 5023 E. 17th St., Indianapolis 1, Ind.
Bruning, John M. ('31; '35) (AS), Oper. Engr., Bd. of Education, 1334 York Ave.; *for mail,* 500 E. 72nd St., New York, N.Y.
Brunkhardt, Fred W. (J'39) (CD), Engrg. Consultant, Charles W. Cromb Co., Cunard Bldg., 220 S. 16th St., Philadelphia 2, Pa.
Brunn, Frederick Milton (J'43) (SCKFM), Jr. Research Engr., Foster Wheeler Corp., 165 Broadway, New York 6, N.Y.
Brunner, Clarence Hargis ('41) (BLS), Mech. Engr., Austin Co., 1924 Broadway, Oakland; *for mail,* 218 Pala Ave., Piedmont 11, Calif.
Brunner, Jules E. (J'43) (SFLKC), Ch. Power Plant Engr., Glidden Co. (& Durkee Famous Foods), 5165 W. Moffat, Chicago 39; *for mail,* 7814 Karlov, Skokie, Ill.
Brunner, Mathias John (J'43) (BKS), 768 E. 52nd St., Brooklyn, N. Y.
Brunot, Albert William ('38; '45) (BNJKG), Mech. Sec. Head, Thomson Lab., Gen. Elec. Co., 920 Western Ave., West Lynn; *for mail,* 19 Falls St., East Lynn, Mass.
Bruns, H. Richard ('45) (SNKLMD), Squad Leader, Mech. Dept., Ebasco Services, Inc., 2 Rector St., New York; *for mail,* 44 Vincent Ave., New Dorp, S.I. 6, N.Y.
Bruns, John Dickson (J'43) (AK), Engr. (Air Conditioning), Boeing Aircraft Co., Seattle; *for mail,* 5111 Hudson St., Seattle 8, Wash.
Bruns, Robert Stewart, Jr. (J'41) (KSOF), 315 Byron Pl., Maywood, N.J.
Brunyate, William Richard (J'43) (AES), 108 Grant Ave., Bound Brook, N.J.
Brupbacher, Benjamin Simon, Jr. (J'45) (ACY), 1556 Paul Morphy St., New Orleans, La.
Brusca, L. Joseph ('30; '31; '35) (NBHY), Sales Engr., SKF Industries, Inc., Front St. & Erie Ave., Philadelphia; *for mail,* 511 Arbor Rd., Cheltenham, Pa.
Brush, C. Benjamin ('31) (CM), Saw Mill Supply Inc., 957 Saw Mill River Rd., Yonkers; *for mail,* 40 Maywood Rd., New Rochelle, N.Y.
Brush, Harold Frank (J'40) (HJKCMR), Indus. Engr., B. F. Sturtevant Co., Div. of Westinghouse Elec. Corp., 31 Clinton St., Newark 2, N.J.
Brusher, William Francis (J'42) (LKOCBN), Engr., Design Sec., Gen. Engrg. Dept., Stand. Oil of Calif., 225 Bush St., San Francisco; *for mail,* 3912 Greenwood Ave., Oakland 2, Calif.
Brusso, Andrew M. (J'44) (BJM), Engrg. Draftsman, Welin Davit & Boat Corp., Perth Amboy; *for mail,* 391 MacArthur Ave., Long Branch, N.J.
Brust, George A. ('45) (LMO), Ch. Planning Engr., Refrigeration Div., Internatl. Harvester Co., U.S. Highway 41, Evansville, Ind.
Bruton, Donald Lee (J'45) (CD), Lt. (j.g.), U.S.N.R.; *for mail,* Apt. 101, 5610 Enright, St. Louis 12, Mo.
Bruzelius, Edward M. ('34; '44) (EFJCLK), Lt. Comdr., U.S.N.R., Officer in Charge, Office of Inspr. of Naval Matl., U.S.N., Westinghouse Elec. Corp., East Pittsburgh, Pa.
Bryan, Alan Stuart (J'35) (KTHBJY), Project Engr., Am. Bemberg Corp., Elizabethton; *for mail,* Box 148, Johnson City, Tenn.
Bryan, Bruce Winfield (J'46) (CKY), 802 S. Ironwood, South Bend, Ind.
Bryan, Edward Everett ('45) (CKS), Supt. Bldgs. & Power Plant, Vanderbilt Univ., 21st Ave. S. & Broad St., Nashville 4, Tenn.
Bryan, Emmett Wren ('42) (SLKJ), Ch. Engr., Lumsden & Van Stone Co., 426—1st St., Boston 27; *for mail,* 14 North St., Stoneham 80, Mass.
Bryan, Herbert Gayle (J'43) (ESFOBK), Head, Internal Combustion Plant Unit, Rural Electrification Admin., U.S. Dept. of Agric., Washington, D.C.
Bryan, John K. (J'40) (SKJF), Engr. Asst. to Mech. Supt., Venice Power Plant, Union Elec. Co. of Mo., Venice, Ill.
Bryan, Justus L. ('30; '35) (BCM), Ch. Draftsman, IMO Pump Dept., De Laval Steam Turbine Co., 853 Nottingham Way, Trenton 2; *for mail,* 1202 Pennington Rd., Trenton 8, N.J.
Bryan, Marcus K. ('16; '35) (FSE), Cons. Engr., Charles T. Main, Inc., 201 Devonshire St., Boston 10, Mass.
Bryan, R. G. (J'39), Capt., 7235 Euclid Ave., Chicago, Ill.
Bryan, Walter Edwin ('14; '20) (SRCFAB), Engr. Consultant & Analyst, St. Louis Pub. Serv. Co., 3869 Park Ave., St. Louis 10, Mo.
Bryan, William Lyttle, Jr. (J'45) (KN), Research Engr., York Corp., York, Pa.
Bryans, Dayton R. (J'38) (WDM), Packaging Engr., Carrier Corp., 300 S. Geddes St., Syracuse 2, N.Y.
Bryans, Henry Bussell ('17; '18) (CDFOSZ), Exec. V.P., Philadelphia Elec. Co., 1000 Chestnut St., Philadelphia 5, Pa.
Bryans, Henry T. (J'40) (FKS), Philadelphia Elec. Co., 1000 Chestnut St., Philadelphia 5; *for mail,* 8 Farm Rd., Wayne, Pa.
Bryans, William R. ('19) (BNWA), Asst. Dean, Prof. Engrg. Mechanics, College of Engrg., N.Y. Univ., Bronx 53, N.Y.
Bryant, Elmer John ('21; '28) (MCJA), Detroit Dist. Mgr., Greenfield Tap & Die Corp., 5850—2nd Blvd., Detroit 2, Mich.
Bryant, James Lewthwaite (J'45) (WOANCS), Jr. Mech. Engr., Pacific Mills, Ltd.; *for mail,* Box 6, Ocean Falls, B.C., Can.
Bryant, Jerrus Madison ('27; '35) (BCJMNY), Ch. Engr., Link-Belt Co., 519 N. Holmes Ave., Indianapolis 8, Ind.
Bryant, John George (J'44) (ANMGBD), Research & Devel. Engr., Am. Chain & Cable Co., Inc., Ross St.; *for mail,* 48 S. River St., Wilkes-Barre, Pa.
Bryant, Lorton William (J'35) (NSACBK), Mech. Engr., Roots-Connersville Blower Corp., Connersville, Ind.
Bryant, P. John, II (J'39) (CDAM), Asst. Managing Secy., Engrg. Soc. of Detroit, 100 Farnsworth, Detroit 2, Mich.
Bryant, Robt. E. (J'18) (BCM), Purchasing Dept., Buffalo Arms Corp., Box C, Sta. E, Buffalo; *for mail,* 314 Washburn St., Lockport, N.Y.
Bryant, William Whitsel (J'35) (CSO), Staff Asst., Elev. Div., Westinghouse Elec. Corp., 150 Pacific Ave., Jersey City 4, N.J.
Bryce, James ('31; '35) (SFEC), Ch. Inspr., Milwaukee Inspc. Dept., Md. Casualty Co. (Baltimore), 611 N. Broadway, Milwaukee 2, Wis.
Bryden, Colby William (J'23), 329 Mountain Ave., Westfield, N.J.
Bryson, William Donal ('45), 2nd Asst. Supt., Internatl. Harvester Co., 5 Pulaski St.; *for mail,* 152 S. Hoopes Ave., Auburn, N.Y.
Bubar, Hudson H. ('19; '21) (OSFD), 15 Park Row, New York 7, N.Y.
Bubar, Willard Clark ('44) (SFC), Field, Design Engr., Bubar Dust Systems, 15 Park Row, New York, N.Y.
Bubb, Milford John ('45) (BJS), M.M., Commonwealth Edison Co., Box 149, Pekin, Ill.
Bublitz, Charles A., Jr. (J'43) (WCRDM), Maj., 576 McKinley St., Gary, Ind.
Buccola, Charles H. (J'30) (NBA), Elec. Designer, Sperry Gyroscope Co., Inc., Great Neck, L.I.; *for mail,* 4155—70th St., Woodside, L.I., N.Y.
Buchan, Lloyd P. (J'39), 413 Centre Square, Milford, Pike Co., Pa.
Buchanan, D. Dwight ('18; '21; '35), 33—6th St., S.E., Massillon, Ohio.
Buchanan, Kenneth Alex (J'42) (ACM), 18 Boswell Ave., Toronto, Ont., Can.
Buchanan, Wm. C. ('18; '35), 419 Columbia Terrace, Peoria, Ill.
Buchberg, Harry (J'41) (AHNKBZ), Research Engr., Lockheed Aircraft Corp., Burbank; *for mail,* 8616 W. 3rd St., Los Angeles 36, Calif.
Buchen, Joseph Clement ('18; '21) (CLMK), V.P., Leslie Salt Co., Newark; *for mail,* 840 Breed Ave., San Leandro, Calif.
Bucher, George Heisler ('44) (ABMRSH), Vice-Chmn., Westinghouse Elec. Corp., 306—4th Ave., Pittsburgh 30, Pa.
Bucher, Paul ('21; '35) (SFHKEB), Prof. Steam Engrg., Ohio State Univ., Columbus 10, Ohio.
Buchhagen, Walter Harry ('44) (CDLKMO), Coordination Engr., Am. Cyanamid Co., 30 Rockefeller Plaza, New York 20, N.Y.
Buchi, Alfred J. (Non-Member), *Melville Medallist,* '37; Büchi Syndicate, 20 Salstr., Winterthur, Switzerland.
Buchmann, Karl Emil ('25; '31; '35) (NBDFOG), Design Engr., McIntyre Porcupine Mines Ltd., Schumacher; *for mail,* 13 Birch St. S., Timmins, Ont., Can.
Buchsbaum, Arnold (J'37) (ENBJ), Mech. Engr., Diesel Design & Testing, N.Y. Naval Shipyard, Brooklyn; *for mail,* 1360—48th St., Brooklyn 19, N.Y.
Buck, Everett S. ('38) (EFKOS), Cons. Mech. Engr., Ft. Wayne Air Conditioning Co., 223 E. Main St., Ft. Wayne 2, Ind.
Buck, Nelson Lewis ('38; '45) (AO), 38 S. Lincoln St., Washington, Pa.
Buck, Robert S. (J'42) (ABL), 2117 Lemon Ave., Temple City, Calif.
Buckalter, Lloyd Arthur (J'44), 156 W. 86th St., New York 24, N.Y.
Buckalter, Robert Irving (J'41) (JAM), Tech. Engr., Air Conditioner Design, Gen. Elec. Co., 5 Lawrence St., Bloomfield; *for mail,* 25 Oxford St., Montclair, N.J.
Buckholtz, Ira Elmer (J'40), Capt., Corps of Engrs., U.S.A., A.P.O. 7511, c/o Postmaster, New York, N.Y.
Buckingham, Earle ('13; '35) (BMA), *Worcester Reed Warner Medallist,* '44; Prof. Mech. Engrg., Mass. Inst. of Tech., Cambridge, Mass.
Buckingham, Walter Harlow (J'38) (ESZFC), Clark Bros. Co., Olean, N.Y.; *for mail,* 173 Davis St., Bradford, Pa.
Buckland, Bruce O. (J'24) (ABS), Gen. Elec. Co., 1 River Rd., Schenectady, N.Y.
Buckley, Frederick Doyle (J'44) (SKRAFB), Research Engr., Battelle Memorial Inst., 305 King St., Columbus; *for mail,* 502 Colonial Ave., Worthington, Ohio.
Buckley, Guidet M. ('22; '25; '35) (ESHR), Retired; 178 Hillcrest Rd., Mt. Vernon, N.Y.
Buckley, Raymond William ('45) (SNFDBH), Ch. Engr., Imperial Paper & Color Corp., Lower Warren; *for mail,* 137 Ridge St., Glens Falls, N.Y.
Buckminster, Lloyd Allen (J'44) (ADH), Devel. Engr., Dept. A13A, Am. Optical Co.; *for mail,* 34 Prospect St., Southbridge, Mass.
Buckowski, Henry John (J'40) (JLM), Capt., 36th Engr. Combat Gp., A.P.O. 541, c/o Postmaster, New York, N.Y.
Buckwalter, Tracy V. ('13) (BFJRTW), Retired; 2301 Del Mar Pl., Ft. Lauderdale, Fla.
Budd, Edward Gowen ('46), *A.S.M.E. Medallist,* '44; Pres., Edw. G. Budd Mfg. Co., 25th St. & Hunting Park Ave., Philadelphia, Pa.
Budd, Ralph (H'43) Pres., Chicago, Burlington & Quincy R.R. Co., 547 W. Jackson Blvd., Chicago 6, Ill.
Budde, Albert A. (J'39) (ZACNBO), Exec. Engr., Instrument Research Div., Natl. Advis. Com. for Aero., Langley Field; *for mail,* 225 Hampton Roads Ave., Hampton, Va.
Budden, Edgar LeRoy (J'45), Devel. Engr., Doubleday & Co., 14 W. 49th St., New York; *for mail,* 10903—86th Ave., Richmond Hill, N.Y.
Buddine, Norman Theodore (J'28) (LKCZH), Process Engr., Stone & Webster Engrg. Corp., 49 Federal St., Boston; *for mail,* 29 Bancroft Rd., Wellesley Hills 82, Mass.
Budell, Robert (J'44) (JMASFL), Blanch Ave., West Norwood, N.J.
Budell, William (J'37) (CSH), Asst. Plant Engr., Congoleum-Nairn, Inc., Cedarhurst; *for mail,* 4 New Windsor Rd., Westminster, Md.
Budenholzer, Roland Anthony (J'42) (SKBEAH), Assoc. Prof. Mech. Engrg., Ill. Inst. of Tech., 3300 Federal St., Chicago 16, Ill.
Budny, Walter Vincent (J'39) (AECM), 2nd Lt., Engrg. Officer, Army Air Forces, Maxwell Field, Ala.; *for mail,* 2691 S. 12th St., Milwaukee 7, Wis.
Budwell, Leigh ('16; '21) (CFR), Ch. Mech. Officer, Richmond, Fredericksburg & Potomac R.R. Co., Richmond 20; *for mail,* 1600 Confederate Ave., Richmond 22, Va.
Budzyko, Edward James, Jr. (J'44) (CAMJON), Lt. (j.g.), U.S.N.R., Naval Serv. Depot, Navy 3149, F.P.O., San Francisco, Calif.; *for mail,* Box 160, R.D. 1, Bristol, Pa.
Buechler, Ralph M. (J'39) (ABK), Maj., Army Air Forces; *for mail,* 631 Main St., Hamilton, Ohio.
Buenger, Edw. F. ('30), V.P., Charge Mfg., Wilson-Jones Co., 3300 Franklin Blvd.; *for mail,* 836 Lathrop Ave., River Forest, Ill.
Buensod, Alfred Charles ('15; '27) (TG), Pres., Buensod-Stacey, Inc., 60 E. 42nd St., New York 17; *for mail,* 33—5th Ave., New York 3, N.Y.
Buerer, Wayne Wallace ('43) (EFSAYZ), Design Engr., Westinghouse Elec. Co., Lester Branch P.O., Philadelphia 13; *for mail,* 438 Sutton Ave., Folsom, Pa.

Buerk, Benjamin Christian (J'31) (MNCJ), Partner, Gen. Mgr., Buerk Tool Works, 315 Grote St., Buffalo 7; *for mail,* 192 High Park Blvd., Eggertsville 21, N.Y.
Buffinton, Alfred L. (J'45) (SFLE), Engr., Babcock & Wilcox Co., 85 Liberty St., New York 6, N.Y.
Buffum, Timothy Nicholson (J'45), Ensign, U.S.N., 890 Urbano Dr., San Francisco 12; *for mail,* 3371 Jackson St., San Francisco, Calif.
Buford, Edwin Hardy ('39) (DLY), Mgr., Design Div., Monsanto Chem. Co., 1700 S. 2nd St., St. Louis 4, Mo.
Bugge, Sven B. ('16) (HKW), V.P., Gen. Mgr., Tomahawk Kraft Paper Co., Tomahawk, Wis.
Buhler, Carl (J'42), 7157—69th St., Brooklyn 27, N.Y.
Bujak, Henry Carl (J'40) (NBAH), Sr. Engr., Vickers Inc., 1400 Oakman Blvd., Detroit 32; *for mail,* 15416 Wildemere Ave., Detroit 21, Mich.
Bukaty, Raymond M. (J'45), Test Engr., Gen. Elec. Co., 1 River Rd., Schenectady, N.Y.
Bulen, William Herman (J'44) (MRNAHJ), 220 E. 10th, Escondido 1, Calif.
Bulger, William Arthur ('43) (CMFK), V.P., Charge of Mfg., Petroleum Heat & Power Co., Southfield Ave.; *for mail,* Route 36, Old N. Stamford Rd., Stamford, Conn.
Bulk, George Kenneth (J'44) (ANJYBG), Designer, Douglas Aircraft Co., Inc., 3000 Ocean Park Blvd., Santa Monica; *for mail,* 717 Swarthmore Ave., Pacific Palisades, Calif.
Bullard, Edward Clarke ('29) (CNM), V.P., Gen. Mgr., Bullard Co., 286 Canfield Ave., Bridgeport 2, Conn.
Bullard, Edw. P. ('13), *A.S.M.E. Medallist,* '37; Pres., Bullard Co., 286 Canfield Ave., Bridgeport 2, Conn.
Bullard, John Ervin (A'13) (AWRCYG), Free Lance Writer, Tech. & Business Articles, Box 38, Central Valley, N.Y.
Bullen, Clarence Kirkwood ('28; '30) (CHOMD), Civilian Prod. Admin., Key Bldg., Oklahoma City 2; *for mail,* 200 N.E. 14th St., Oklahoma City 4, Okla.
Bullinger, Clarence Edward ('24; '35) (CMDO), Prof., Head, Dept. of Indus. Engrg., Pa. State College; *for mail,* 637 West Foster Ave., State College, Pa.
Bullock, Harry Leslie ('44) (YLMCTN), Dir., Bullock-Smith Associates, 136 Liberty St., New York 6, N.Y.
Bullock, Joseph B. (J'36) (SFKJ), Asst. to Supt., Power Prod. Stas., Consltd. Gas, Elec. Light & Power Co. of Baltimore, Lexington Bldg., Baltimore 3; *for mail,* 1940 Breitwert Ave., Baltimore 30, Md.
Bullock, Richard Gould (J'41) (MSWRCD), Lt., U.S.N.R.; 4333—1st Ave., N.E., Seattle 5, Wash.
Bullwinkel, Herman Henry ('44) (EKS), Dist. Turb. Engr., Cent. Dist., Gen. Elec. Co., 840 S. Canal St., Chicago 80, Ill.
Bumgardner, Harvey Edward ('40) (SCYFZ), Supvr. of Library & Secy., Pat. Com., Detroit Edison Co., 2000—2nd Ave., Detroit 26, Mich.
Bump, Burton Nelson ('92; '04) (OFSAKC), 120 Clifton Pl., Syracuse 6, N.Y.
Bumstead, Robert (J'40) (ACY), Engr., Mfrs. Mutual Fire Ins. Co., 10 Weybosset St., Providence 1, R.I.; *for mail,* 5513 Morris St., Philadelphia 44, Pa.
Bunce, John Peter (J'45) (JMR), Asst. Adv. Mgr., Kearney & Trecker Corp., West Allis 14; *for mail,* 3119 N. 26th St., Milwaukee 6, Wis.
Bunevich, Robt. R. (J'39) (BCS), Draftsman, Navy Dept., Anacostia, D.C.; *for mail,* 158 Gregory Ave., Passaic, N.J.
Bunge, Ralph W. ('15; '26) (BCDFJK), Asst. Cons. & Supvg. Engr., Stand. Brands, Inc., 595 Madison Ave., New York, N.Y.
Bunke, Edward William Diedrich (J'36) (BEA CMJ), Design Engr., Gen. Elec. Co., 1 River Rd., Schenectady 5, N.Y.
Bunker, Henry Lloyd, Jr. ('42) (EKL), Process Engr., E. I. du Pont de Nemours & Co., Wilmington 98, Del.
Bunker, Philip Dearborn (J'36) (LBDJSW), Engr., Cheney-Bigelow Wire Works, 417 Liberty St.; *for mail,* 105 High St., Springfield, Mass.
Bunker, Richard Davidson (J'45) (CMDSJO), Seaman, 1st Class, U.S.N., Draftsman, Pub. Works Bldg. 131, Naval Trng. Center, Great Lakes, Ill.; *for mail,* 458 Essex St., Lynn, Mass.
Bunker, Warren W. (J'41) (SEM), 6507 Sefton Ave., Baltimore 14, Md.
Bunker, William Beehler ('43) (BDR), Lt. Col., U.S.A., New Orleans Procurement Office, Trans. Corps, Box 285, New Orleans 9, La.
Bunker, William L. ('23) (CFM), Cosmopolitan Shipping Co., 42 Broadway, New York, N.Y.; *for mail,* 54 Ardsley Rd., Montclair, N.J.
Bunn, Edward S. ('41) (JKL), Revere Copper & Brass, Inc., 1301 Wicomico St., Baltimore, Md.
Bunn, William Bennett, Jr. ('45) (JPS), Welding Engr., M. W. Kellogg Co., Box 469, Jersey City, N.J.

Cecil, Robert E. ('21) (CJ), V.P., Sales, Scaife Co., Oakmont; *for mail,* 1402 N. Negley Ave., Pittsburgh 6, Pa.
Cederborg, Gibson Ames (J'44) (AHBNEM), Mech. Engr., Natl. Advis. Com. for Aero., Langley Field; *for mail,* Apt. 4, 260 Regent St., Hampton, Va.
Ceely, Frederick Jesse (J'43) (KBSHCL), Design Engr., Steam Div., Foster Wheeler Corp., 165 Broadway, New York 6; *for mail,* 146-30 Huxley St., Rosedale, N.Y.
Cehrs, Charles H. (J'40) (AEM), Engrg. Draftsman, Boeing Aircraft Co., Georgetown Sta., Seattle; *for mail,* 1225 E. Northlake, Seattle 5, Wash.
Cejka, Joseph B. (J'41) (MOAJBC), Asst. Prof. Mech. Engrg., Rutgers Univ., New Brunswick, N.J.
Cella, John Thomas (J'44), 37 Washington Sq. W., New York, N.Y.
Cernea, Roland Emanuel ('41) (BCDJMN), Plant Engr., Pa. Forge Corp., Milnor & Bleigh Sts., Philadelphia 35; *for mail,* Apt. 10, 5051 Oxford Ave., Philadelphia 24, Pa.
Cerny, Walter J. ('30; '37) (ABCMNO), Dir. Engrg., Northrop Aircraft, Inc., Northrop Field, Hawthorne; *for mail,* 5960 Tuxedo Terrace, Hollywood 28, Calif.
Cerreto, Sebastian Salvatore (J'44), 22—10th St., New London, Conn.

Cesarz, William John, Jr. (J'45) (FJS), U.S. Navy; 757—1st St., Westfield, N.J.
Chadwick, Jean Stuart (J'39) (FK), Engrg. Cartographer, Aircooled Motors Corp., Liverpool Rd., Syracuse; *for mail,* 320 Wellesley Rd., Syracuse 7, N.Y.
Chadwick, Lee Sherman ('99; '09) (BCEFHJ), Pres., Chmn. of Bd., Perfection Stove Co., 7609 Platt Ave., Cleveland 4, Ohio.
Chadwick, Norman Howard (J'43) (CHND), John Robertson Co., Inc., 133 Water St., Brooklyn 1, N.Y.; *for mail,* 1231 Cambridge Ave., Plainfield, N.J.
Chafee, John S. ('26; '35) (CMNT), V.P., Saco-Lowell Shops, 60 Batterymarch St., Boston 10, Mass.; *for mail,* 245 President Ave., Providence 6, R.I.
Chaffe, William H. ('22) (CDMN), Works Mgr., Simmons Co., Brunswick Ave., Elizabeth F; *for mail,* Box 122, Meridith Rd., Colonia, N.J.
Chaffee, Rupert A. (J'38) (BEP), Serv. Engr., Clark Bros. Co., Inc., Olean, N.Y.; *for mail,* 125 W. 1st St., Tulsa, Okla.
Chaffey, Edmund Kilbourne, Jr. (J'42) (NOESG), Mech. Engr., Pur. Dept., Westinghouse Elec. Corp., East Pittsburgh; *for mail,* 3027 Mt. Allister Rd., Pittsburgh 14, Pa.
Chaffin, Warren Leland ('29; '35) (CMSTDA), Exec. V.P., J. L. Stifel & Sons, Inc., Main & 4th Sts., Wheeling, W. Va.
Chaharyn, Orist D. (J'45), Capt., Co. C, 1st Trng. Bn., Camp Ritchie, Md.
Chalfant, Arthur I. (J'41) (BHKE), Research Engr., Baker Mfg. Co.; *for mail,* 12 N. 2nd St., Evansville, Wis.
Chalkley, Curtis Rathbone ('16; '24) (BJKMNR), Mech. Engr., Navy Dept., 35 E. 7th St., Cincinnati 2, Ohio; *for mail,* 40 Beechwood Rd., Ft. Mitchell, Ky.
Chalkley, Henry G. ('08), Sweet Lake Land Oil Co., Lake Charles, La.
Challies, John Bow ('43) (SCH), V.P., Exec. Engr., Shawinigan Water & Power Co., 107 Craig St. W., Montreal 1, Que., Can.
Challman, Arnold Telfer (J'44) (ZCLBEJ), Sales Engr., Minneapolis-Honeywell Regulator Co., 1136 Howard St., San Francisco 3, Calif.
Chambellan, Rene Edmond (J'46) (BCL), 537 St. Pauls Ave., Cliffside Park, N.J.
Chamberlain, Gordon Lyle (J'31) (RJMNEB), Engr., N.Y. Air Brake Co., Starbuck Ave.; *for mail,* 315 California Ave., Watertown, N.Y.
Chamberlain, Leon Hoyt ('25; '35) (HZYLJA), East. Mgr., Am. Well Works, 475—5th Ave., New York 17; *for mail,* 766 Palmer Rd., Bronxville 8, N.Y.
Chamberlin, John Maurer (J'43) (YLJMAB), Tool Engr., Plastics Div., Monsanto Chem. Co., Monsanto Ave.; *for mail,* 61 Oak St., Indian Orchard, Mass.
Chamberlin, John Windsor ('43) (TKEJO), Pres., Appliance Corp. of Am., 430 E. Silver Spring Rd., Milwaukee 11, Wis.
Chamberlin, William T. ('17) (EFKS), Mech. Engr., Dept. of Pub. Works, City of New York, 125 Worth St., New York 7, N.Y.
Chambers, Edwin Graydon ('32; '42) (CMDLJ), Engr., Mfg. Processes, West. Elec. Co., Inc., 2600 Broening Highway, Baltimore; *for mail,* 7312 Yorktown Dr., Towson 4, Md.
Chambers, Henry Edward, Jr. ('31) (ESC), Lt. Col., Corps of Engrs., U.S.A., c/o A.M. Lockett & Co., 401 Magnolia Bldg., Dallas, Tex.
Chambers, James Wesley (J'43) (JRDELO), Inspr., La. Div., Stand. Oil Co. of N.J., Box 551, Baton Rouge 1; *for mail,* 3739 Perkins Rd., Baton Rouge 15, La.
Chambers, Norman Campbell ('05; '14) (EJMN), Retired; 40 E. 54th St., New York 22, N.Y.
Chambers, William Henry (J'38) (NCJMBY), Mech. Design Draftsman, Submarine Sig. Co., 160 State St., Boston; *for mail,* 154 Cedar St., East Dedham, Mass.
Chambers, William R. ('21; F'45) (CDFHOS), Cons. Engr., Clinton Engrg. Works, Tenn. Eastman Corp.; *for mail,* R.D. 6, Holston Hills, Knoxville, Tenn.
Champion, Albert R. (J'40) (NKEAZS), Scripps Inst. of Oceanography, Univ. of Calif., La Jolla, Calif.
Champion, C. H. ('33), Managing Dir., Charles H. Champion & Co. Ltd., 99 Howard's Lane, Putney, London, S.W. 15, England.
Champion, Edward Lees (J'44) (SHK), V.P., Gibbs & Hill, Inc., Pa. Sta., New York 1, N.Y.
Champion, Noel Martin (J'43), Aviation Radio Technician, 3rd Class, Carrier Aircraft Serv. Unit, F9, F.P.O., San Francisco, Calif.; *for mail,* 1302—1st Ave. E., Spencer, Iowa.
Champlin, Donald Webb ('42) (MJC), V.P., Gen. Mgr., Defiance Mch. Works, Inc., Defiance, Ohio.
Champney, Ralph Preston ('16; '35) (CDLMY), Pres., Mitchell & Smith, Inc., 9501 Copland Ave., Detroit 17, Mich.
Chan, Albert So (J'43) (KSMNHA), Design Draftsman, Mar. & Struc. Engr., Bethlehem Steel Corp., 20th & Illinois St., San Francisco; *for mail,* 241½ N. Humboldt Rd., San Mateo, Calif.
Chan, Wellington K. (J'41) (BCMAZG), Lab. Engr., Ward Leonard Elec. Co., 31 South St., Mount Vernon; *for mail,* 37-38—65th St., Woodside, N.Y.
Chandler, Arthur Hall (J'43) (MCA), 40 Howard St., Reading, Mass.
Chandler, Edward Farrington ('45) (AOS), Engr. (Consultant), 148 Richmond St., Brooklyn 8, N.Y.
Chandler, Harry Stuart, Jr. (J'40) (HLM), Engr., Defence Indus., Ltd., Box 10, Montreal; *for mail,* 65B Cedar Ave., Shawinigan Falls, Que., Can.
Chandler, Howard McCune ('13) (ABR), 109-28—212th St., Bellaire, Queens Village 9, N.Y.
Chandler, Lawrence Fowler (J'43) (MCJ), 2010½ Chamberlain Ave., Chattanooga 4, Tenn.
Chandler, Marland Hewes (J'40) (SOFCL), Pacific Gas & Elec. Co., 245 Market St., San Francisco, Calif.
Chandler, Orville Woodrow (J'42) (NABCJM), Mech. Design Engr., Gen. Elec. Co., 1 River Rd., Schenectady 5; *for mail,* 2112 Hugh St., Schenectady, N.Y.
Chandler, Robert (J'34) (CDM), Apt. 3 N, 175 Linwood, Buffalo 9, N.Y.
Chandler, Thompson ('46) (CJK), Chem. Engr., Carbide & Carbon Chemicals Corp., Box N, S. Charleston 3, W. Va.
Chandler, William Charles (J'41) (CES), Cadet Engr., Pub. Serv. Elec. & Gas Co., 80 Park Pl., Newark, N.J.; *for mail,* 2193 E. 21st St., Brooklyn 29, N.Y.
Chaney, Alex Fred (J'41) (HLMBJA), Design Engr., Simmons Mfg. Co.; *for mail,* 241 Pearl St., Ashland, Ohio.
Chaney, George Hall, Jr. (J'45) (ACW), c/o Mrs. C. J. Greene, 759 Middlefield Rd., Palo Alto, Calif.
Chankalian, Robert H. (J'39) (CMG), Electronic Technician's Mate, 3rd Class, U.S.N., Naval Research Lab., Washington 20, D.C.; *for mail,* 505 Post Ave., Lyndhurst, N.J.
Channappa, B. K. ('45), Mysore Iron & Steel Works, Bhadravati, India.
Chanoux, Theodore (J'43) (COMA), 826 E. 234th St., Bronx, N. Y.
Chao, Eugene (J'45) (SEFKOB), Asst. Engr., Stone & Webster Engrg. Corp., 49 Federal St., Boston 7; *for mail,* 38 Divinity Hall, Harvard Univ., Cambridge 38, Mass.
Chao, Pei Hua (J'43) (FKS), Serv. Engr., Combustion Engrg. Co., Inc., 200 Madison Ave., New York 16, N.Y.
Chao, Wu Wai (J'45) (BJEMNT), 290 Massachusetts Ave., Cambridge 39, Mass.
Chapin, B. R. (J'42) (ASC), Field Serv. Rep., United Aircraft Serv. Corp., East Hartford, Conn.; *for mail,* 243 S. Crestway, Wichita, Kan.
Chapin, George W. (J'36) (CPS), Lt. Comdr.; 213 North C, McAlester, Okla.
Chapin, Warren Winthrop ('17) (WJ), Cons. Engr., 2 W. 45th St., New York 19, N.Y.; *for mail,* 354 Highland Ave., South Norwalk, Conn.
Chaplin, Frank Sprague ('42) (BRJA), Research Engr., The Franklin Inst., 20th St. & Parkway, Philadelphia 3; *for mail,* 822 Glendalough Rd., Philadelphia 18, Pa.
Chaplin, John H. ('20; '26; '27), Veeder-Root, Inc., Hartford, Conn.
Chapman, Edmund Earle ('44), Mech. Asst., Atchison, Topeka & Santa Fe Ry. Co., 1033 Ry. Exchange Bldg., 80 E. Jackson Blvd., Chicago; *for mail,* 229 N. Humphrey, Oak Park, Ill.
Chapman, Edward Corbin ('45) (JLNSFB), Ch. Metallurgist, Combustion Engrg. Co., Inc., 1032 W. Main St., Chattanooga 1, Tenn.
Chapman, Everett ('43) (JARBKY), Consultant, Box 387, Coatesville; *for mail,* R.F.D. 4, West Chester, Pa.
Chapman, John Barton (J'45) (BCJMZ), Process Engr., Remington Arms Co., Inc., 939 Barnum Ave., Bridgeport; *for mail,* 7 Lalley Blvd., Fairfield, Conn.
Chapman, Paul Allen ('43), Acting Gen. Plants Mgr., Am. Bemberg Corp., N. A. Rayon Corp.; *for mail,* 235 F St., Elizabethton, Tenn.
Chapman, Reginald Ernest (J'44) (CD), Factory Mgr., Internatl. Business Mchs. Co., Ltd., 300 Campbell Ave. W., Toronto 9, Ont., Can.
Chapman, Robert Gorham ('36; '44) (NMC), Chmn., Dept. Mech. Engrg., Univ. of Vt., Burlington, Vt.
Chapman, Robert Hett ('19; '24; '27) (TCS), V.P., Asst. Treas., Riverdale Mills & Inman Mills, Box 1714, Spartanburg, S.C.
Chapman, Semmes, Jr. (J'42) Lt. (j.g.), U.S.N.R., 4117 Gosnold Ave., Norfolk, Va.
Chapman, W. Lewis ('41) (LS), Exec. Engr., Mich. Sugar Co., 2nd Natl. Bank Bldg.; *for mail,* 116 Garden Lane, Saginaw, Mich.
Chapman, William Cullen (J'46), Lt., Army Air Forces, 1504th Base Unit, Fairfield, Calif.

Coston, Charles Leslie (J'39) (BSZ), Assoc. Ord. Engr. (P-3), Design & Drafting Div., Sec. 8 (Pamphlets), Naval Shipyard, 11th & N St., S.E., Washington 25; *for mail*, 2814 Q St., S.E., Washington 20, D.C.
Cotter, Chester ('37) (OSEF), Engr., Black & Veatch, Cons. Engrs., 4706 Broadway, Kansas City 2; *for mail*, 2019 Erie St., North Kansas City 16, Mo.
Cotter, George Louis ('24; '45) (RCHA), Asst. West. Mgr., Westinghouse Air Brake Co., 80 E. Jackson Blvd., Chicago 4, Ill.
Cotterell, Wm. J. ('24) (FKS), Managing Dir., Internatl. Combustion, Ltd., P.O. Box 5981, Johannesburg, S. Africa.
Cotterman, Frank David (J'36) (BNZJ), Research Engr., Crane Co., 836 S. Michigan Ave., Chicago 5, Ill.

Cottle, Arthur P. ('35) (AEJ), Retired; 632 Home Ave., Oak Park, Ill.
Cottle, Harry Norman, Jr. (J'41) (ABZJ), Project Engr., Exper. Sec., Propeller Div., Curtiss-Wright Corp., Caldwell; *for mail,* 31 E. Highland Ave., Orange, N.J.
Cottle, Richard Arnold (J'40) (DEL), Sales Engr., Independent Rubber Co., 665 W. Washington Blvd.; *for mail,* 632 Home Ave., Oak Park, Ill.
Cotton, Edwin Ray ('38; '40) (S), Sales Engr., Gen. Elec. Co., 570 Lexington Ave., New York 22, N.Y.
Cotton, Howard W. ('42) (BMN), H. W. Cotton Co., 535—5th Ave., New York 17, N.Y.
Cottrell, Frederick G. (Non-Member), *Holley Medallist,* '37; Consultant, Research Corp., 405 Lexington Ave., New York 17, N.Y.; *for mail,* 1557 Waverly St., Palo Alto, Calif.
Cottrell, Nicholas (J'40), 6911 Beverly Rd., Bethesda, Md.
Cottrell, Robert Boyd, Jr. (J'41) (RMJCAD), Capt., Ord. Dept., Instr., Officer Candidate Sch., Aberdeen Proving Ground, Md.
Cottrell, Robert Boyd, Sr. ('41) (RCJMB), Ch. Mech. Engr., Am. Steel Fdys., 410 N. Michigan St., Chicago 11, Ill.
Couch, Charles William (J'38) (KB), Assoc. Mech. Engr., Puget Sound Naval Shipyard; *for mail,* 1136 Evans Ave., Bremerton, Wash.
Couch, David H. ('19) (SFK), Mech. Engr., Ebasco Services, Inc., 2 Rector St., New York 6; *for mail,* R.F.D. 3, Douglas Rd., Beachcroft, Huntington, L.I., N.Y.
Couch, Harold Kennan (J'41), Serv. Engr., Babcock & Wilcox Co., 105 S. La Salle St., Chicago 3, Ill.
Coulson, Armand Leroy (J'43) (CMZAHS), Lt. (j.g.), U.S.N.; *for mail,* 712 Lorentz Ave., Morgantown, W. Va.
Coulson, Harry Glen ('28) (NCDEAZ), Design Engr., Noble Co., 1860—7th St., Oakland 7; *for mail,* 961 Tulare Ave., Berkeley 6, Calif.
Coulter, Earl Eugene (J'43) (ABE), 17735 Parkmount Ave., Cleveland 11, Ohio.
Coulter, Warren Raymond ('44), Ch. Engr., Coulter Copper & Brass Co., Ltd., 115 Sumach St.; *for mail,* 21 Donlea Ave., Toronto, Ont., Can.
Coupal, Eugene A. ('46) (CMO), 30 Norwich Rd., Needham, Mass.
Coupland, Bertram Russell (J'41), Engr., Charge Design & Tool & Equipment, Super-Cold Corp., 1020 E. 59th St.; *for mail,* 9611 S. LaSalle St., Los Angeles, Calif.
Courtenay, Mortimer Hasell ('36) (TC), Field Engr., SKF Industries, Inc., 591 Peachtree St., N.E.; *for mail,* 2590 Forrest Way, N.E., Atlanta, Ga.
Courtney, A. W. Jr. (J'39) (ABS), Capt., Hdq., 5th Army Air Force, A.P.O. 925, c/o Postmaster, San Francisco, Calif.
Courtney, Albert Lee (J'43) (MBLZDO), Prod. Engr., Studebaker Corp., Sample St.; *for mail,* 519 Gladstone Ave., South Bend 19, Ind.
Coutinho, John DeSiqueira (J'42) (ABM), Graduate Aero. Engr., Grumman Aircraft Engrg. Corp., Bethpage; *for mail,* 10-A Bennett Gardens, Hempstead, N.Y.
Couture, Joseph Walter ('44), Ch. Engr., Diltj Mch. Works, North 1st; *for mail,* R.F.D. 1, Fulton, N.Y.
Couzins, Newton W. (J'39) (CJM), Ch. Engr., Berkeley Steel Constr. Co., Inc., 2nd & Camelia Sts.; *for mail,* 249 Yale Ave., Berkeley, Calif.
Covey, Kenneth S. ('43), 509 Anderson St., Pittsburgh, Pa.
Covino, Adolph O. ('40), 2431 Dean St., Brooklyn, N.Y.
Cowan, Alfred Vanterhoit (J'41) (LYKZEF), Chem. Engr., Research, Koppers Co., Inc., Koppers Bldg., Pittsburgh 19; *for mail,* 2 Olympia Pl., Pittsburgh 17, Pa.
Cowan, Ben (J'32) (LWHNB), Mech. Engr., Price Bros. & Co., Ltd., Kenogami; *for mail,* 33-204 Notre Dame St. W., Montreal, Que., Can.
Cowan, Edw. L. (J'38) (CFS), Asst. Ch. Engr., Gaylord Container Corp., Bogalusa, La.
Cowan, Frank ('21) (ACDHKM), Ch. Engr., Arnold Bros. Inc., Perry, Iowa.
Cowan, James H. (J'40) (EOCLSF), Mgr., Utilities, City of Spur, Spur, Tex.
Cowan, Percy J. ('37; F'38), Upcott, Cranes Park, Surbiton, Surrey, England.
Cowell, Allan Tyler (J'43) (FAKJE), Asst. Automotive Engr., Atlantic Refining Co., 3144 Passyunk Ave.; *for mail,* 5855 N. 6th St., Philadelphia 20, Pa.
Cowell, Warner T. ('25) (NMJABL), Gear Engrg. Dept., Gleason Works, 1000 University Ave., Rochester; *for mail,* 32 Hartsdale Rd., Rochester 9, N.Y.
Cowgill, William Warwick ('33) (YTACMO), Project Mgr., U.S. Rubber Co., 1230—6th Ave., New York 20, N.Y.; *for mail,* Greenfield Hill, Fairfield, Conn.
Cowie, Alexander ('37) (BJNAH), Research Engr., Foote Bros. Gear & Mch. Corp., 5225 S. Western Ave., Chicago 9; *for mail,* 3017 E. 78th St., Chicago 49, Ill.
Cowles, Clifford Atwood ('17; '25) (SZLEFK), Owner, Cowles & Co., 1112 Texas Bank Bldg., Dallas 2, Tex.
Cowles, William Eddy (J'42) (ACD), Test Engr., Gen. Elec. Co.; *for mail,* 1038 Dean St., Schenectady, N.Y.
Cox, Abraham Beekman ('14) (SBA), Maj., Ord., Field Serv., Retired; Glensfoot Farm, Cherry Valley, N.Y.
Cox, Clarence Edward ('29) (BEK), Ch. Engr., Engrg. Dept., Chicago Pneumatic Tool Co., Howard St.; for mail, 1324 Chestnut St., Franklin, Pa.
Cox, Edward Lorenz ('23; '45) (BEHKYW), Specification & Design Engr., Navy Dept., 17th St. & Constitution Ave., Washington; *for mail,* 1620 Ft. Davis St., S.E., Washington 20, D.C.
Cox, Felix Otterbine, Jr. (J'42) (FZM), Instrument Mechanic, Bethlehem Steel Co., Sparrows Point; *for mail,* 2903 Dunmore Rd., Baltimore 22, Md.
Cox, Frank G. ('05; A'08), 2415 W. 17th St., Wilmington 73, Del.
Cox, Harold Newton, Jr. (J'37), Tech. Sgt., Ord., U.S.A., Hdq. & Supply Co., 140th Ord. Bn., A.P.O. 505, c/o Postmaster, New York; *for mail,* Southold, L.I., N.Y.
Cox, James Cleo ('38), Foreman, Welding-Copper Shop, Tenn. Eastman Corp.; *for mail,* Route 3, Cliffside, Kingsport, Tenn.
Cox, James S. (J'39) (BCJ), 728 Delaware Ave., Bethlehem, Pa.
Cox, James William ('16; '21) (CDT), Textile Engr., 320 Broadway, New York 7, N.Y.
Cox, John Lyman ('27) (JBHKL), Ch. Engr., Midvale Co., 4320 Wissahickon Ave., Philadelphia 40, Pa.
Cox, John Thomas, Jr. (J'43), 3632 Meadowlake, Houston, Tex.
Cox, Len (J'44) (MJNB), Test Engr., MacDonald & MacDonald, 718 Granville St.; *for mail,* 3436 W. 36th Ave., Vancouver, B.C., Can.
Cox, Osborne S. (J'38) (ZMJNY), Gage Designer, A.C. Spark Plug Div., Gen. Motors Corp., Flint 2; *for mail,* 635 N. Ball St., Owosso, Mich.
Cox, S. F. ('29), Research Librarian, Research Lab., Pittsburgh Plate Glass Co., Creighton, Pa.
Cox, William Paul (J'21) (BRJNYM), Mech. Engr., Ry. Div., Timken Roller Bearing Co., 1835 Dueber Ave., S.W., Canton 6, Ohio.
Coxon, Wilfred R. ('45) (SFK), Steam Engr., Solvay Process Co., Hopewell, Va.
Coykendall, William Ellis, Jr. (J'42), 56 Prospect Ave., Larchmont, N.Y.
Coyle, Daniel K. ('40) (ABC), 878 Acacia St., Sunnyvale, Calif.
Coyle, William G., Jr., (J'39), 331—4th St., Atlanta, Ga.
Cozzo, Sam Edmund ('36) (BLKD), Ch. Draftsman, Charge Designing, Austin Co., Engrs & Bldrs., Pittsburg; *for mail,* 363 Santa Clara Ave., Oakland 10, Calif.
Crabb, Gordon Henry ('43) (BHNMYC), Mech. Engr., Panama Canal, Balboa Heights; *for mail,* Box 564, Gamboa, C.Z.
Crabill, John Willard (J'42) (AJMFSC), Lead Preliminary Tool Engr., Boeing Aircraft Co., 7755 E. Marginal Way; *for mail,* 13342—34th Ave. S., Seattle 88, Wash.
Craft, Harry William (J'44) (CL), Mech. Foreman, Procter & Gamble Mfg. Co., 169 E. Grand, St. Louis 7; *for mail,* 5345 N. Kingshighway, St. Louis 15, Mo.
Crafton, Paul A. (J'44) (NMBCYZ), Mech. Engr., Research & Devel., Naval Research Lab.; *for mail,* 3940—2nd St., S.W., Washington 20, D.C.
Crafts, Curtis S. ('34) (GBCMY), Secy., Ch. Engr., Goss Ptg. Press Co., 1535 S. Paulina St., Chicago 8, Ill.
Crafts, Irving M. ('34), Pres., Pickering Governor Co.; *for mail,* 485 Main St., Portland, Conn.
Craig, Burnie McDonald ('38; '44) (ONBZ), Cons. Mech. Engr., 934 El Campo Dr., Pasadena 8, Calif.
Craig, Gordon Davis (J'45) (SMCKOE), Instr., Mech. Engrg., Univ. of Santa Clara, Santa Clara; *for mail,* 845 California St., San Francisco, Calif.
Craig, Howard B. (J'99), Retired; 161 Orchard Rd., Solvay 9, N.Y.
Craig, Jas. ('97), Retired; 3900 Post Rd., Apponaug, R.I.
Craig, John McKinley (J'44) (CKABDJ), Area Engr., E. I. du Pont de Nemours & Co.; *for mail,* Apt. 3, 1712 West St., Wilmington, Del.
Craig, John S. (J'36) (SKD), Sales Engr., Babcock & Wilcox Co., 2730 Koppers Bldg., Pittsburgh 19, Pa.
Craig, Ollison ('21) (FSKCJN), Engrg. Mgr., Riley Stoker Corp., 9 Neponset St.; *for mail,* 245 Burncoat St., Worcester, Mass.
Craig, Robert ('18; '24) (ABCES), Pat. Atty., Cooper, Kerr & Dunham, 233 Broadway, New York 7, N.Y.
Craig, William Hardy (J'43) (YLKSC), Constr. Supvr., Dow Chem. of Can. Ltd., Sarnia, Ont., Can.
Crain, Henry Lawson ('28; '39) (SFE), Plant Results Engr., Kansas City Power & Light Co., 115 Grand St., Kansas City 6, Mo.
Crain, John J. ('96; '08), E. Main St., Wallingford, Conn.
Crain, Richard Willson, Sr. (J'38) (SKDNLJ), Instr., Mech. Engrg. Dept., Univ. of Wash., Seattle 5, Wash.
Crais, Charles I. (J'38), Standard Elec. Time Co., Springfield 2, Mass.
Cramer, Jerome Paul (J'36) (DCNMLJ), Supt., Mch. Shop, Bay City Iron Works, 475—4th St., Oakland 7; *for mail,* 761 Spruce St., Berkeley 7, Calif.
Cramer, Luther William (J'32) (DB), Real Estate Agent, 231 N.E. 7th Ave., Camas, Wash.
Cramer, Robert, Jr. (J'31) (EBSN), Asst. Ch. Engr., Nordberg Mfg. Co., 3073 S. Chase Ave., Milwaukee 7; *for mail,* Box 184, Hales Corners, Wis.
Crane, Edw. J. ('25), West. Elec. Co., Inc., Chicago; *for mail,* 623 N. Kenilworth Ave., Oak Park, Ill.
Crane, Eugene C. ('15; '22) (FJKS), Checker, Lee Wilson Engrg. Co., 20005 West Lake Rd., Rocky River; *for mail,* 2203 Eldred Ave., Lakewood 7, Ohio.
Crane, Harry O. (J'37), Lt., Picatinny Arsenal, Dover, N.J.
Crane, Henry Middlebrook ('20) (AE), Tech. Asst. to Chmn., Gen. Motors Corp., 1775 Broadway, New York; *for mail,* 40 E. 54th St., New York 22, N.Y.
Crane, Howard P. ('28; '32) (BMR), 593 Prospect St., West Boylston, Mass.
Crane, Robert Douglas (J'38) (CDJMOY), Sales Promotion, Wilmington Shops, E. I. du Pont de Nemours & Co., Maryland Ave., Wilmington, Del.

Crawford, Ian Cameron ('44) (CDM), 44 Franklin Terrace, Southbridge, Mass.
Crawford, James Vaile (J'40) (HKJLAB), Research Engr., Airesearch Mfg. Co., 9851 Sepulveda Blvd.; *for mail,* 8107 Airlane Ave., Los Angeles 45, Calif.
Crawford, Kenneth Zschokke (J'45) (BCM), Jr. Design Engr., Ford Instrument Co., Inc., 32-36—47th Ave., Long Island City 1; *for mail,* 49-30 Forest Dr., Douglaston, N.Y.
Crawford, M.H. (J'39) (FKS), Dow Magnesium Corp., Ludington, Mich.
Crawford, Melvin Wilbur (J'45) (MBCNO), 2535 Dunstan Rd., Houston 5, Tex.
Crawford, William F. ('43) (CSMJHK), Pres., Edward Valves, Inc., 1200 W. 145th St., East Chicago, Ind.; *for mail,* 6851 Constance Ave., Chicago 49, Ill.
Crawley, George Edwin ('08; '28) (CY), Gen. Mgr., Francisco Sugar Co., Francisco, Camagüey, Cuba.
Crawshaw, S. Leroy ('41) (CMBAEJ), West. Gear Works, 417—9th Ave. S., Seattle 4, Wash.
Creager, Paul Snyder ('45) (ZSL), Assoc. Prof. Elec. Engrg., Rutgers Univ., New Brunswick, N.J.
Crede, Charles E. (J'36) (BYTNAR), Ch. Engr., L. N. Barry Co., Inc., 179 Sidney St., Cambridge 39, Mass.
Crede, Richard E. (J'42) (CM), Gen. Mgr., Allkern Engrg. Co., 71 N. Clinton St., East Orange, N.J.; *for mail,* 201-18—109th Ave., Hollis 7, N.Y.
Credo, Julius ('16; '35), 2111 Edgehill Rd., Louisville 5, Ky.
Creech, Merl Daniel ('38; '44) (BNKLOH), Assoc. Prof. Mechanics, Univ. of Okla., Norman, Okla.

Creed, Edward Merrill (J'41) (BJS), 44 E. Washington St., Rutland, Vt.
Creel, William Hunt ('40) (ACEKL), Office Mgr., Phillips Petroleum Co., Bartlesville, Okla.
Crego, Donald Frank (J'41) (BESMHY), Mech. Engr., McCulloch Engrg. Corp., 3420 W. Capital Dr., Milwaukee 9, Wis.
Crenshaw, Bransford W. ('24; '34; '35) (CMJRLS), Sales Engr., Scullin Steel Co., 6700 Manchester St., St. Louis 10; *for mail,* 120 Orchard Ave., Webster Groves 19, Mo.
Crenshaw, William F. (J'37) (MPS), Petroleum Engr., Delta Drilling Co., Tyler, Tex.; *for mail,* 317 Edwards St., Ft. Collins, Colo.
Creutz, C. Emil ('39) (KLTWY), V.P., Am. Heat Reclaiming Corp., 1270—6th Ave., New York 20, N.Y.
Creveling, Doyle R. (J'45) (MNLBD), Engr., Am. Steel Band Co., Carnegie; *for mail,* 4810 Brownsville Rd., Pittsburgh 10, Pa.
Crewdson, Henry ('19) (BHOTY), Ch. Oper. Engr., Am. Viscose Corp., 35 S. 9th St., Philadelphia 7, Pa.
Crews, J. F. (J'39) (KLB), Ch. Engr., Design & Erection Process Equip., West. Condensing Co., 935 E. John St., Appleton, Wis.
Crews, Lloyd Albert (J'43) (HKS), 1st Lt., Army Air Forces; 84 N. Dearborn St., Indianapolis, Ind.
Crewson, George G. ('15; '19) (LKYTZF), Ch. Engr., Buffalo Electrochemical Co., Sta. B, Buffalo; *for mail,* 45 Coolidge Dr., Snyder, Buffalo 21, N.Y.
Crimp, George Bertram ('23; '32) (SJKFAD), Mech. Engr., Bur. of Engrg., Comptroller, City of New York, Rm. 625, Municipal Bldg., New York; *for mail,* 81 Columbia Heights, Brooklyn 2, N.Y.
Criner, Harry Everett (J'40) (BOAKH), Devel. Engr., Westinghouse Elec. Corp., East Pittsburgh; *for mail,* 17 Marion, Forest Hills, Pittsburgh 21, Pa.
Criswell, J. Carl, Jr., (J'38) (DCLMO), Engr., Am. Stores Co., 424 N. 19th St., Philadelphia 30, Pa.
Criswell, Wilbur Wilson, Jr. ('28; '44) (FSO), Fuel Consultant, United Eastern Coal Sales Corp., 420 Lexington Ave., New York 17, N.Y.
Critchlow, Howard Thompson, Jr. (J'44) (ACJ), Maj., Army Air Forces, 577 Rutherford Ave., Trenton 8, N.J.
Critz, Robert George (J'42) (BRS), Box 128, Shawnee, Okla.
Critzer, Ray D. (J'40) (CJM), 329 E. 326th St., Willoughby, Ohio.
Crocker, Allen S. ('05) (O), Private Cons. Engr., 311 Alexander St., Rochester 7, N.Y.
Crocker, George Holmes ('45) (CJM), Comdr. (Exec. Officer), Naval Ord. Plant, South Charleston, W. Va.
Crocker, John Walter ('38; '44) (SNEMLC), Sandy Hill Iron & Brass Works, Hudson Falls, N.Y.
Crocker, Sabin ('21; '25) (SFBEKH), *Junior Award, '23;* Sr. Engr., Mech. System Engrg. Dept., Detroit Edison Co., 2000—2nd Ave., Detroit 26; *for mail,* 1037 Yorkshire Rd., Grosse Pointe Park 30, Mich.
Crocker, Sabin, Jr. (J'41) (SHBD), Asst. Engr., Shipbldg. Div., Bethlehem Steel Co., Quincy 69; for mail, 662 Main St., Hingham, Mass.
Crockett, Chas. H. ('18; '21; '35) (BW), Sales Engr., 221 Stow Ave., Troy, N.Y.
Crockford, Richard Hallas ('23; '28; '35) (FS), Mech. Engr., Reliance Engrg. Co., Box 1292, Charlotte 1; *for mail,* 1405 Pecan Ave., Charlotte 4, N.C.
Crofoot, George Emerson ('07; '13) (SRFWY), Prof. Mech. Engrg., Univ. of Pa., Philadelphia 39; *for mail,* 4535 Pine St., Philadelphia 43, Pa.
Croft, Huber Ogilvie ('20; '29; '32) (SKEF), *Manager,* '40-'43; Head Dept. of Mech. Engrg., Univ. of Iowa, 122 Engrg. Bldg., Iowa City, Iowa.
Croghan, John T. ('09; '14) (FCYLSN), Mech. Engr., Boston Woven Hose & Rubber Co., 29 Hampshire St., Cambridge 38; *for mail,* 574 Chestnut St., Waban 68, Mass.
Croke, Charles V. (J'41) (CJM), Falk Corp., 3001 W. Canal St., Milwaukee; *for mail,* 2512 N. 53rd St., Milwaukee 10, Wis.
Croker, Morris C. (J'39) (KFESO), Assoc. Mar. Engr., Puget Sound Naval Shipyard; *for mail,* 1215—4th St., Bremerton, Wash.
Croley, Jack G. (J'37), Capt., Btry. B, 113th Antiaircraft Arty. Gun Bn. (Mobile), A.P.O. 4774, c/o Postmaster, New York, N.Y.
Croll, Raymond H. ('26; '32; '35) (EHS), Dist. Mgr., Worthington Pump & Mchy. Corp., Rm. 2821, 436—7th Ave., Pittsburgh 19, Pa.
Cromer, Orville Charles ('40) (EF), Assoc. Prof. Mech. Engrg., Purdue Univ., Lafayette; *for mail,* 261 S. Salisbury St., West Lafayette, Ind.
Crompton, Edward Everett ('45) (BCDM), Pres., Gen. Mgr., Burke Elec. Co., 1202 Cranberry St.; *for mail,* 4424 Homeland Blvd., Erie, Pa.
Cromwell, Oliver C. ('14) (JKR), Retired; 2217 Elsinor Ave., Baltimore, Md.
Crone, James Murray ('45) (OCMAYZ), 402 W. Buffalo St., Ithaca, N.Y.
Cronemeyer, Henry C. ('12) (FKS), Designer, Jones & Laughlin Steel Corp., Aliquippa; *for mail,* 259 College Ave., Beaver, Pa.
Cronin, Frank Howard ('17), Mech. Engr., Natl. Vulcanized Fibre Co., Yorklyn, Del.
Cronin, John Robert (J'43) (MCAS), 7936 Clyde Ave., Chicago 17, Ill.
Crook, Frank P., Jr. (J'46), 1001 S. Windsor Blvd., Los Angeles, Calif.
Crooks, Homer L. (J'41) (KSFCL), Design Engr., C. F. Braun & Co., 1000 S. Fremont St., Alhambra; *for mail,* 801 S. Montecito Dr., San Gabriel, Calif.
Crooks, William Adam (A'44) (CJM), 6971 Dartmouth Ave., St. Louis, Mo.
Crosby, Edwin Stanislau ('21) (CKS), Pres., Johns-Manville Internatl. Corp., 22 E. 40th St., New York 16, N.Y.; *for mail,* 7 Washington Pk., Maplewood, N.J.
Crosby, George Frederick, Jr. ('34; '42) (BCJ), 596 Terrace Pl., Westfield, N.J.
Crosby, Robert William ('45) (ZLCW), Partner, Salesman & Engr., Crosby & Siegars, Co., 98 Exchange St., Portland 3; *for mail,* R.F.D., Raymond, Me.
Cross, Bertram J. ('36) (FKRSZ), Research Engr., Combustion Engrg. Co., Inc., 200 Madison Ave., New York 16, N.Y.
Cross, Bertram J., Jr. (J'41), Route 9-W, Grand View, Nyack, N.Y.
Cross, Garett P. S. ('13) (NBJ), Research Div., United Shoe Mchy. Corp., Elliott St.; *for mail,* 6 Clifton Ave., Beverly, Mass.
Cross, Harold W. ('20) (EFKS), Dist. Turbine Specialist, Gen. Elec. Co., 840 S. Canal St., Chicago 80, Ill.
Cross, Louis Frederick, Jr. (J'40) (OELFHN), Design Engr., Tide Water Associated Oil Co., E. 22nd St., Bayonne; *for mail,* 35 Kensington Ave., Jersey City 4, N.J.
Cross, Malcolm Albert (J'45) (LSD), Mech. Engr., Pa. Salt Mfg. Co., 1000 Widener Bldg., Philadelphia 7; *for mail,* 120 Rodgers St., Ridley Park, Pa.
Cross, Robert Ames ('21; '35) (P), Deere & Co.; *for mail,* 2335—23rd Ave., Moline, Ill.
Cross, Robert C. ('30; '36) (FNM), Head, Mech. Div., Dept. 817, Sears, Roebuck & Co., 925 S. Homan Ave., Chicago 7, Ill.
Cross, Sherman S. ('43; '44) (ACHJMN), Asst. to Supt., Weatherhead Co., E. 131st St., Cleveland; *for mail,* 241 Monroe St., Cuyahoga Falls, Ohio.
Cross, Wallace Jackson ('14; '21), (LKEFSH), Asst. Ch. Designing Engr., Sinclair Refining Co., 3500 Indianapolis Blvd., East Chicago, Ind.
Crossan, Thomas Edmund ('25; '35) (SFCKBE), Supt. Prod., Gulf States Utilities, Florida St., Baton Rouge 2, La.
Crossen John ('43) (JLM), Mech. Engr., Chem. Warfare Serv., War Dept., Dugway Proving Ground, Tooele, Utah.
Crossley, Francis Rendel Erskine (J'44) (BNEG), Visiting Lecturer (Asst. Prof.), Yale Univ., 400 Temple St., New Haven 11, Conn.

Faig, John Theodore ('97; '05; F'43) (CMS), Pres. of Depts., Ohio Mechanics Inst., 1104 Walnut St., Cincinnati 10, Ohio.
Faile, E. H. ('31), R.F.D. 1, Westport, Conn.
Failmezger, Eugene (J'33), Air Appliance Div., U.S. Hoffman Mchy. Corp., Syracuse; *for mail,* 109 Wellington Rd., Dewitt, N.Y.
Fairbanks, Charles Miguel ('25; '37) (BLJCM), Design Engr., Gen. Elec. Co., 9601 Elmwood Ave., Philadelphia 42, Pa.
Fairchild, Charles Owen ('44) (BKZY), Consultant, 114-74—78th Pl., St. Albans, N.Y.
Fairchild, Frederick P. ('15; '26) (SEFJB), Ch. Engr., Elec. Engrg. Dept., Pub. Serv. Elec. & Gas Co., 80 Park Pl., Newark 1, N.J.
Fairchild, Sherman M. (A'27), Chmn. of Bd., Fairchild Eng. & Airplane Corp., 30 Rockefeller Plaza; *for mail.* 17 E. 65th St., New York, N.Y.
Fairchild, Wesley Lee (J'45) (KFBCZ), Jr. Engr., Furnace Engrg. Dept., Corning Glass Works, Corning, N.Y.
Faires, Virgil M. ('28; '32) (NSJEKC), Head, Mgmt. Engrg. Dept., Agric. & Mech. College of Tex., College Station, Tex.
Fairfield, John Guthrie ('17; '25; '35) (KBSEFZ), Prof. Heat Engr., Rensselaer Poly. Inst., 110—8th St., Troy, N.Y.
Fairhurst, Kirk S. (J'38), Capt., Army Air Forces, 1636 Camden Ave., Los Angeles 25, Calif.
Fairhurst, Thurstan William ('41), Dir., Ruston & Hornsby, Ltd.; *for mail,* Imperial House, 15-19 Kingsway, London, W.C. 2, England.
Fairley, George G. (J'41) (EABR), Engrg. Draftsman, Phillips Petroleum Co.; *for mail,* 2029 Osage, Bartlesville, Okla.
Fairman, Seibert ('31; '35) (BA), Prof. Engrg. Mechanics, Purdue Univ., West Lafayette, Ind.
Fairman, Stanley Wright ('33; '43) (CMFDSE), Engr., Consumer Products Div., Corning Glass Works; *for mail,* 201 Watauga Ave., Corning, N.Y.
Faison, George Washington, III (J'43) (ACMFKS), 2nd Lt., Army Air Forces, Flight Engr., 680th Sqd., 504th Gp., A.P.O. 336, c/o Postmaster, San Francisco, Calif.; *for mail,* c/o Stuart Moore, Lexington, Va.
Falcon, Joseph Albert (J'43) (SAE), Jr. Mech. Engr., Gibbs & Cox, Inc., 21 West St., New York 6; *for mail,* 83 Van Sicklen St., Brooklyn 23, N.Y.
Fales, Henry Hammett ('13) (STOLDK), Cons. Engr., 408 Grosvenor Bldg., Providence 3, R.I.
Fales, Herbert Gordon ('21; '33) (JA), V.P., Internatl. Nickel Co., Inc., 67 Wall St., New York 5, N.Y.
Fales, James Nelson True ('45) (BEJ), Engrg. Dept., Wolverine Motor Works, Inc., 35 Union Ave., Bridgeport 2, Conn.
Falk, Edward A. (J'38) (AZF), Lt. (j.g.), U.S.N.R., Ship Repair Unit, Naval Shipyard, Mare Island, Vallejo, Calif.
Falk, George Elias (J'34) (NMBJ), Sr. Mech. Engr., Applied Physics Lab., The Johns Hopkins Univ., 8621 Georgia Ave., Silver Spring, Md.
Falk, Harold Sands ('16) (CDJM), Pres., Falk Corp., 3001 W. Canal St., Milwaukee 8, Wis.
Falk, Melvin L. (J'36) (ABHW), Stress Analyst, Beech Aircraft Corp.; *for mail,* Route 4, Wichita, Kan.
Falkner, Jefferson Cameron ('23; '35) (BCFJKM), Mgr., Elec Prod. Dept., Consltd. Edison Co. of N.Y., Inc., 4 Irving Pl., New York 3, N.Y.
Falkovich, Oleg C. ('41) (KBAHNW), Research Engr., Bonneville Power Admin., Box 3537, Portland, Ore.
Falla, Fernando ('23), Spec. Designer, Foster Wheeler Corp., 165 Broadway, New York 6, N.Y.; *for mail,* 59 Elm St., Maplewood, N.J.
Fallon, John (J'10) (JFCKGZ), Chmn., Managing Dir., Incandescent Heat Co., Ltd., Cornwall Rd., Smethwick, Birmingham; *for mail,* 82 St. Bernard's Rd., Olton, Warwickshire, England.
Falls, Eugene K. (J'32) (SEBC), Asst. Prof. Mech. Engrg., Univ. of Rochester, River Campus, Rochester 3, N.Y.
Falvey, Jeremiah Alfred (J'41) (BASHCF), Design Engr., Aviation Gas Turbine Div., Westinghouse Elec. Corp., Lester Branch P.O., Philadelphia 13; *for mail,* 815 Summit Ave., Prospect Park, Pa.
Fambro, George W. (J'41) (ABC), Draftsman, Glenn L. Martin Co.; *for mail,* Cent. Y.M.C.A., 24 W. Franklin St., Baltimore, Md.
Fangboner, Harold Frank (J'37) (NMHB), Project Engr., John Bean Mfg. Co., 735 E. Hazel, Lansing 4, Mich.
Fangemann, Wm. Howard (J'36) (BGM), Charge Engrg. Records, Intertype Corp., 360 Furman St.; *for mail,* 300 Sterling St., Brooklyn, N.Y.
Fanjul, Higinio Charles (J'35) (CDM), Asst. Mgr., Cespedes Sugar Co., Central Cespedes, Camagüey, Cuba.
Fankhauser, Arnold Franklin Eaton (J'43) (CDOMAJ), Design Engr., Plant Engrg. Dept., Gen. Elec. Co., 1635 Broadway; *for mail,* 1020 McKinnie Ave., Ft. Wayne, Ind.
Fannon, William Alsop ('07) (DFKNSW), Pres., Treas., Fannon Trading Co., Inc., 206 W. College Ave., Appleton, Wis.
Fanshier, Chester ('43) (CGZYJB), Pres., Metal Goods Mfg. Co., 106-110 S. Park, Bartlesville, Okla.
Farbar, Leonard (J'36) (HK), Process Engr., Avon Refinery, Tide Water Associated Oil Co.; *for mail,* 10 Como St., Daly City, Calif.
Farber, Erich Alexander (J'43) (MBK), Lowry Hall, Columbia, Mo.
Fardelmann, John Henry ('18; '22; '27) (COS), Mech. Engr., M. H. Treadwell Co., 140 Cedar St., New York 6, N.Y.; *for mail,* 217 Alexander Ave., Montclair, N.J.
Faridany, H. P. (J'38) (CHS), Pipe Line Supt., Kermanshah Petroleum Co. Ltd., Kermanshah, Iran.
Farin, William George (J'45) (KLP), Jr. Engr., E. I. du Pont de Nemours & Co., Box 993, Charleston 24; *for mail,* 1524 B Washington E., Charleston 1, W.Va.
Farintosh, Henry Ernest (J'44) (ASBCMJ), Canadian Natl. Carbon Co. Ltd., Davenport Rd., Toronto; *for mail,* 11-A Silverbirch Ave., Toronto 8, Ont., Can.
Farkas, Thomas Paul (J'42) (BCLMZ), Mech. Engr., Mem. Tech. Staff, Bell Tel. Labs., Inc., 463 West St., New York 14; *for mail,* 34-40—79th St., Jackson Heights, L.I., N.Y.
Farley, James Joseph (J'40) (ANEBM), Aero. Engr., Naval Air Matl. Center, Naval Base, Philadelphia; *for mail,* 1623 N. 60th St., Philadelphia 31, Pa.
Farmer, Edward H. ('41) (ACMLDJ), Supt. Fabrication, Lockheed Aircraft Corp.; *for mail,* 4366 Clybourn Ave., Burbank, Calif.
Farmer, F. Malcolm ('15), V.P., Cons. Engr., Elec. Testing Labs., 79th St. & East End Ave., New York, N.Y.
Farmer, George Coburn ('44) (BCR), Commercial Engr., Westinghouse Air Brake Co., Wilmerding, Pa.
Farmer, John Taylor ('40) (SFEHLC), Mech. Engr., Montreal Engrg. Co., Ltd., 244 St. James St., Montreal, Que., Can.
Farmer, William Crawford ('45) (ACBJM), Lt. Col., Plans & Policies Officer, Ord. Dept., U.S.A., Rm. 4 E 372, The Pentagon, Washington 25, D.C.
Farnell, George (J'44) (EKJF), Mech. Engr., Research Project, Mass. Inst. of Tech., 77 Massachusetts Ave.; *for mail,* 46 Massachusetts Ave., Cambridge 39, Mass.
Farnham, Duane Wesley (J'34) (EFLSKA), 2621 E. 20th St., Tulsa, Okla.
Farnham, George Wright ('16; '25; '35) (CAMBJN), V.P., Irwin-Farnham Publ. Co., 332 S. Michigan Ave., Chicago 4, Ill.
Farnham, Roger Durfee (J'42), Lt. (j.g.), U.S.N., T.T.S.A., Naval Air Sta., Banana River, Cocoa, Fla.
Farnham, Walter E. ('18; '35), Prof. Graphics, Head of Dept., Engrg. Sch., Tufts College, Medford, Mass.
Farnsworth, Augustus Page ('43) (COMA), Partner, Coverdale & Colpitts, 120 Wall St., New York 5, N.Y.
Farnsworth, Paul L. (J'41) (ABE), 3712 Highland Ave., Drexel Hill, Pa.
Farquhar, Bannister Wells ('40) (JCSKB), Engr., Gulf Oil Corp.; *for mail,* 4525 Alamosa Dr., Port Arthur, Tex.
Farquhar, Francis ('07) (C), V.P., Chmn. of Bd., A. B. Farquhar Co., 142 N. Duke St.; *for mail,* Box 1432, York, Pa.
Farquhar, Lloyd Carleton ('19; '35) (CJR), Works Mgr., East St. Louis Works, Am. Steel Fdys., 2039 E. Broadway, East St. Louis, Ill.
Farr, Arthur V. ('37) (Y), Pres., Farr Engrg. Co., 300 E. 43rd St., New York 17, N.Y.; *for mail,* 44 Clinton Ave., Maplewood, N.J.
Farr, Eric Martin (J'45) (FJABSZ), Test Engr., Wright Aero. Corp., Beckwith Ave., Paterson; *for mail,* Packanack Lake, N.J.
Farr, Morrill Spencer (J'35) (MJBKLY), Asst. Gen. Mgr., Secy., Treas., Farr Co., 2615 Southwest Dr., Los Angeles 43, Calif.
Farrar, D. Franklin, Jr. (J'40) (ABW), Design Draftsman, Plant Engrg. Dept., Nashville Div., Consltd. Vultee Aircraft Corp., Couchville Pike; *for mail,* 4109 Belmont Blvd., Nashville 4, Tenn.
Farrell, Eugene Francis (J'36) (BKE), Devel. Engr., Detroit Gear Aircraft Parts Div., Borg-Warner Corp., 12345 Kercheval St., Detroit; *for mail,* 1602 Anita St., Grosse Pointe Woods 30, Mich.
Farrell, Frederick L. ('13; '21; '35) (BEFKSW), Dist. Mgr., Combustion Engrg. Co., Inc., 80 Federal St., Boston; *for mail,* 4 Bay State Rd., Belmont 78, Mass.
Farrell, Jas. A., Jr., (J'24), Pres., Am. South African Line, Inc., 26 Beaver St., New York, N.Y.
Farrell, Joseph Milton ('33; '35) (AEMOCN), Classification Coder, War Assets Corp., Pratt & Whitney Plant, Kansas City, Mo.; *for mail,* 121 N. Yale St., Wichita 8, Kan.
Farrell, Raymond Patrick ('44) (CJM), Secy., Treas., Harper Packing Co., 312 Patterson, Chester; *for mail,* 821 Kerper St., Philadelphia 11, Pa.
Farrington, Stephan G. ('41) (ZSLMCO), V.P., Gen. Mgr., Foster Engrg. Co., 109 Monroe St., Newark; *for mail,* 35 Beverly Rd., West Orange, N.J.
Farrington, Stephen John, Jr. (J'42) (CMD), Methods Engr., De Laval Steam Turbine Co., Trenton 2; *for mail,* 834 Berkeley Ave., Trenton 8, N.J.
Farris, Marshall Elmer ('35) (HMNRS), Dean, College of Engrg., Univ. of New Mex., Albuquerque, New Mex.
Fassbender, Walter J. (J'22) (SBJKHF), Designing Engr., Yarnall-Waring Co., 102 E. Mermaid Lane, Philadelphia 18; *for mail,* 7636 New 2nd St., Philadelphia 26, Pa.
Fassett, Donald G. (J'37) (CDNW), Asst. Engr., Mch. Design, Ederer Engrg. Co., 2931—1st Ave. S., Seattle 4; *for mail,* Box 778, R.F.D. 1, Port Blakely, Wash.
Faulkner, C. L. (J'36) (LS), Soybean Mill, Swift & Co.; *for mail,* 52 S. O'Neal St., Frankfort, Ind.
Faulkner, David S. ('12; '13; '35) (CEJ), V.P., Natl. Supply Co., Torrance, Calif.
Faus, Herbert Williams ('41) (RFJSC), Engr. M.P., N.Y. Cent. System, 466 Lexington Ave., New York 17, N.Y.
Faust, H. M. ('30; '35) (FSEC), Research Engr., Mgr. Coal Devel., N.Y. Coal Co., 150 E. Broad St., Columbus 15; *for mail,* 2873 E. Cleft Dr., Columbus 8, Ohio.
Faust, Per Alexander ('21) (BCDFKN), M.M., Maint. Engr., Internatl. Smelting & Refining Co., Inspiration; *for mail,* Box 1057, Miami, Ariz.
Fava, Albert Anthony ('45) (SFLMD), Ch. Engr., Atlantic Gelatin Co., Inc., Hill St., Woburn, Mass.
Faville, Frederick Alden ('44), Pres., Faville-Le Vally Corp., 105 W. Adams St., Chicago 3, Ill.
Fax, David Hirsch (J'38) (BSKNC), Engr., Steam Turbine Dept., Allis-Chalmers Mfg. Co., Milwaukee 1; *for mail,* 2639 N. 46th St., Milwaukee 10, Wis.
Fay, Charles H. ('27) (FHS), Cons. Engr., 216 Glen Ave., Millburn, N.J.
Fay, John A. (J'40) (ACM), Jr. Prod. Engr., Lockheed Aircraft Corp., Burbank; *for mail,* 6449 Wilkinson, North Hollywood, Calif.
Fay, Joseph Edmund (J'39) (C), Mgr., U.S. Employment Serv.; *for mail,* 211 Wyoming Ave., West Pittston, Pa.
Fay, Oscar Karl ('43) (CKZSGF), Prod. Supt., Twin Branch Plant, Ind. & Mich. Elec. Co., Mishawaka, Ind.
Fay, Robert Clovis (J'45) (ENSBJK), Ensign, U.S.N.R., PC-1147, F.P.O., San Francisco, Calif.
Fayerweather, Frederick Oakley, Jr. (J'38) (AC), Serv. Rep., Military Liaison, Wright Aero. Corp., 132 Beckwith Ave., Paterson 3, N.J.
Faymonville, Philip R. ('18; '25; '35) (CYD), Col., Gen. Staff Corps, Hdq., 4th Serv. Comd., 526 Old Post Office Bldg., Atlanta 3, Ga.
Feagles, Ralph L. ('12) (BCDM), Pat. Engr., Exec., Black Sivalls & Bryson, Inc., 2131 Westwood Ave., Oklahoma City, Okla.
Fearnside, Thomas Astley ('44) (EKORS), Mech. Engr., Stone & Webster Engrg. Corp., 49 Federal St., Boston 7; *for mail,* 33 Wall St., Wellesley 81, Mass.
Fechheimer, Carl J. ('27) (KHB), 1930 N. Prospect Ave., Milwaukee 2, Wis.
Fedde, Arnold M. (J'33), 454—9th St., Brooklyn 15, N.Y.
Fedenia, John N. (J'40), Ensign, U.S.N.R., 2508 W. National Ave., Milwaukee 4, Wis.
Federici, Frank (A'44) (CLO), Dir., Associated Indus. Consultants, Broad St. Bank Bldg., Trenton 8, N.J.
Fee, Harold Rollins ('21; '28; '35) (CES), Office Mgr., Ingersoll-Rand Co., 11 Broadway, New York 4; *for mail,* 17 Wyndmere Rd., Mt. Vernon, N.Y.
Feeley, Edward Joseph, Jr. (J'41) (ABH), 30 Rhode Island Ave., N.W., Washington, D.C.
Fegel, Arthur C. ('41) (WMCJ), Mfg. Engr., West. Elec. Co., Inc., 100 Central Ave., Kearny; *for mail,* 9 English Village, Cranford, N.J.
Feicht, Edward R. ('07; '17) (SFOT), Head, Firm of Edward R. Feicht, Cons. Engrs., 111 Old Lancaster Rd., Bala-Cynwyd, Pa.
Feicht, Edward R., Jr. (J'41) (AMC), 1st Lt., Army Air Forces, Air Tech. Serv. Comd., Wright Field, Dayton, Ohio; *for mail,* 111 Old Lancaster Rd., Bala-Cynwyd, Pa.

Feiereisen, William John (J'43) (ASEFKO), U.S. Navy, Hdq. Sqd., Fleet Air Wing 3, F.P.O., New York, N.Y.; *for mail,* 207 James St., Beaver Dam, Wis.
Feige, William Frederick (J'35) (NBHJC), Designing Engr., H. R. Krueger Co., 1469 E. Grand Blvd., Detroit; *for mail,* 26395 Humber St., Huntington Woods, Mich.
Feiker, Fred'k M. (A'12) (CT), Dean, Sch. of Engrg., The George Washington Univ., Washington, D.C.
Feil, George William, Jr. (J'44) (NJBAZ), Research Engr., Aluminum Research Labs., Aluminum Co. of Am., New Kensington, Pa.
Fein, Mitchell (J'45), Dir. of Engrg., Consltd. Mgmt. Consultants, 521—5th Ave., New York 17, N.Y.
Feinberg, Milton (J'42) (AMHBS), 1451 S. Beverly Dr., Los Angeles 35, Calif.
Feiner, Hyman L. (J'40) (CTMAGL), Ch. Engr., Consultant, S. Liebovitz & Sons, Inc., 75 Leonard St., New York 13, N.Y.; *for mail,* 2312 N. 2nd St., Harrisburg, Pa.
Feiner, Mark Anthony ('42) (CMLDJN), Secy., P. Feiner & Sons, Inc., 522 W. 45th St., New York 19, N.Y.
Feinstein, Lester (J'40) (BJM), 226 B. 141st St., Belle Harbor, L.I., N.Y.
Feitl, Rudolph Raymond (J'43) (BN), Engr., Otis Elevator Co., 260—11th Ave., New York, N.Y.; *for mail,* 5405 Bergenline Ave., West New York, N.J.
Fehr, Roy Benner ('14; '19; '23) (MNJBEK), Dir., Engrg. & Sales, Schaefer Elec. Products Co., 5680—12th St., Detroit 8; *for mail,* 704 Forrestdale Rd., Royal Oak, Mich.
Felber, George S. (J'40) (JLM), Specifications Engr., Am. Can Co., 320 Elizabeth Ave., Newark 8; *for mail,* 636 Buchanan St., Hillside, N.J.
Felberg, Leonard (J'37) (AEM), Foreman, Republic Aviation Corp., Farmingdale; *for mail,* 942 E. 14th St., Brooklyn 30, N.Y.
Felch, Robert Irving (J'41) (CMSJHL), Systems Analyst, Indus. Engrg. Dept., RCA-Victor Div., Radio Corp. of Am., Camden, N.J.; *for mail,* 8617 Evergreen Ave., Chestnut Hill, Philadelphia 18, Pa.
Feld, Louis (J'41) (SHNOEC), Mech. Engr., Centrifugal Engrg. Div., Worthington Pump & Mchy Corp., Harrison; *for mail,* 390 Hawthorne Ave., Newark, N.J.
Feldman, Abram M. ('00) (O), Retired; 320 Central Park W., New York 25, N.Y.
Feldman, Morton Marvin (J'43) (BKS), 938 S. Townsend St., Syracuse, N.Y.
Feldman, Nathan R. (J'42) (LMSJZ), Sr. Engr., Research & Devel., Philco Corp., C & Tioga Sts., Philadelphia 34; *for mail,* 926 Tabor Rd., Philadelphia 41, Pa.
Felgar, James Huston ('16) (CGKL), Dean Emeritus, College of Engrg., Univ. of Okla., Norman, Okla.
Feliu, Carlos J. (J'39) (CSFLDZ), Mgr., Indus. Mchy. Div., Garcia Commercial Inc., Stop 6½, Fernandez Juncos Ave., San Juan; *for mail,* Box 363, 13 Prince St., San Juan 2, P.R.
Felix, Samuel Palmer, Jr. (J'40) (CJM), Asst. Supt., North Plant, De Laval Steam Turbine Co., Trenton 2, N.J.; *for mail,* The Molecule-Yardley Rd., Morrisville, Pa.
Felker, George F. ('13; '15; '18) (MS), V.P., Crosby Steam Gage & Valve Co., Rm. 1728, 165 Broadway, New York 6, N.Y.
Fell, Hugh Parrish ('15; '19) (LWMDS), Prod. Mgr., Casein Div., Borden Co., 350 Madison Ave., New York 17, N.Y.
Fellers, Clark I. (J'41) (MNLOCB), Plant Engr., Navy Ord. Div., Eastman Kodak Co., 50 Main St. W., Rochester 4; *for mail,* 322 Lake Ave., Rochester 6, N.Y.
Fellinger, Robert Cecil (J'44) (NSJMBZ), 320 Lewis St., Burlington, Iowa.
Fellows, Julian Robert ('41) (FKMJ), Prof. Mech. Engrg., Univ. of Ill., Urbana, Ill.
Fellows, Olin Burt ('19; '35) (CMB), Pres., Ideal Wrapping Mch. Co., 81 Sprague Ave., Middletown, N.Y.
Felt, Wright L. ('38) (CSEFH), Regional Engr., Fed. Works Agency, 1206 Santee, Los Angeles 1; *for mail,* 256 El Camino Dr., Beverly Hills, Calif.
Felten, Jos. M. ('27) (BCL), R.F.D. 1, Kingston, Ga.
Felton, George W. ('21) (CJM), 252 Commonwealth Ave., Boston 16, Mass.
Fendel, Fred A. (J'41) (NCYAJ), Lt. (j.g.), U.S.N.R., Staff, Fleet Air Wing 8, Naval Air Sta., Alameda, Calif.; *for mail,* 151 Nixon Ave., Staten Island 4, N.Y.
Fendrich, V. William (J'40) (CGR), Assoc. Inspr. of Naval Matls., 30 Church St., New York 7; *for mail,* 474—8th St., Brooklyn, N.Y.
Feng, Tze-Pei ('45) (DLO), c/o F. D. Loo, Bank of Kiangsu, 371 Kiangse Rd., Shanghai, China.
Fennel, Charles K. (J'40) (CDL), Sales Engr., Internatl. Gen. Elec. Co., 570 Lexington Ave., New York 22, N.Y.
Fennell, Arthur Richard, Jr. (J'38) (HJM), Sr. Draftsman, Design Gages, Greenfield Tap & Die Corp., Sanderson St.; *for mail,* 42 Abbott St., Greenfield, Mass.
Fenning, James F. ('45), 515 Jackson Ave., Bridgeport, Conn.
Fenton, Clifford Monroe ('45) (BCDLNS), Design Supvr., De Laval Steam Turbine Co., Nottingham Way, Trenton 2; *for mail,* 1928 Pennington Rd., Trenton 8, N.J.
Fenwick, Harold Helvie ('29) (GCA), Assoc. Prof., Univ. of Louisville, 3rd & Eastern Pkwy., Louisville 8, Ky.
Ferar, Robt. (J'34), Engr., Testing Lab., U.S. Radiator Co., 127 N. Campbell; *for mail,* 2689 Boston Blvd., Detroit, Mich.
Ferguson, Allan R. (J'34) (BAMC), Mgr., Aircraft Devices Div., Foote Bros. Gear & Mch. Corp., 5225 S. Western Blvd., Chicago; *for mail,* 338 N. Ashland Ave., La Grange, Ill.
Ferguson, Cedric Keith (J'43) (KSH), Lt. (j.g.), S-E, U.S.N.R., Engrg. Exper. Sta., Annapolis; *for mail,* 418 Severn Ave., Eastport, Md.
Ferguson, Donald Adams (J'45) (AES), Ensign, U.S.N.; *for mail,* 428 Yale Ave., New Haven 15, Conn.
Ferguson, Donald McHardy (J'39) (MCD), Methods & Stands. Engr., E. D. Jones & Sons Co., Depot St., Pittsfield, Mass.
Ferguson, Hardy Smith ('99; F'41) (HLS), Partner, Hardy S. Ferguson & Co., 200—5th Ave., New York 10, N.Y.
Ferguson, Harry J. (J'41) (CHK), Plant Engr., Resisto Pipe & Valve Co., 262 Bridge St., East Cambridge; *for mail,* 243 Metropolitan Ave., Roslindale, Mass.
Ferguson, James Rex (J'43) (AKNHEW), Engrg. Designer, N. Am. Aviation, Inc., 5601 Imperial Way, Inglewood; *for mail,* 848 S. Oxford Ave., Los Angeles 5, Calif.
Ferguson, John Emil (J'40) (MC), Mch. Designer, Marathon Corp., Menasha; *for mail,* 508 Oak St., Neenah, Wis.
Ferguson, John F. ('31) (OSRLKN), Prin., Ferguson Engrs., 17 Queen St. E., Toronto 1, Ont., Can.
Ferguson, Louis A., Jr. ('21; '35), Customer's Serv. Mgr., Commonwealth Edison Co., 72 W. Adams St., Chicago, Ill.
Ferguson, Morris S. (J'44) (DEJNR), Engr., Indus. Hygiene, Dust & Fume Control, Am. Smelting & Refining Co., Garfield; *for mail,* Apt. 10, 153—2nd Ave., Salt Lake City 3, Utah.
Ferguson, Ray T. (J'38) (JSL), Ch. Engr., Graham Mfg. Co. Inc., 415 Lexington Ave., New York 17, N.Y.
Ferguson, Reginald ('29) (MJCNFA), Dir., Charge of Prod., F. Perkins (Diesels) Ltd., Queen St., Peterborough, Northants, England.
Ferguson, Robert Bruen ('19; '26) (LKNCDS), R.F.D. 1, Glassboro, N.J.
Ferguson, Robert Ireland (J'39) (JMBCND), Tool Engr., Greenfield Tap & Die Corp., Sanderson St., Greenfield, Mass.; *for mail,* 5202 W. Roosevelt Dr., Milwaukee 10, Wis.
Ferguson, William ('32) (KS), Asst. Supvg. Engr., Travelers Ins. Co., 700 Main St., Hartford 15, Conn.
Ferguson, William Burder ('43) (ACW), 52 Garden Pl., Brooklyn 2, N.Y.
Fernald, Ernest Mercer ('18; '28) (BKSEFO), Prof. Mech. Engrg., Lafayette College; *for mail,* R.D. 2, Easton, Pa.
Fernald, Henry B., Jr. (J'32) (ABYSJ), Metal. Coordination Supvr., Wright Aero. Corp., 132 Beckwith Ave., Paterson 3; *for mail,* 81 Gordonhurst Ave., Upper Montclair, N.J.
Fernandez, A. (J'40), Cia. Azucarera America, Central America, Oriente, Cuba.
Fernow, Bernhard Edward ('28) (EFHKS), Prof. & Head, Mech. Engrg. Dept., Clemson College, Clemson, S.C.
Fernstrom, F. S. ('17; '31; '35) (CDJMY), Mgr., Spec. Serv. Dept., Ernst & Ernst, 123 S. Broad St., Philadelphia; *for mail,* 5515 Wissahickon Ave., Philadelphia 44, Pa.
Ferrara, Norman ('45) (BCDJLS), Head Gen. Engrg. Dept., Colgate-Palmolive-Peet Co., 105 Hudson St., Jersey City 2; *for mail,* Box 683, New Brunswick, N.J.
Ferrari, Frank A. (J'38) (SEFR), Engr., Maint. Dept., Symington-Gould Corp., 20 Symington Pl., Rochester 11; *for mail,* 44 Madison St., Rochester 8, N.Y.
Ferrari, Luigi Mario (J'38) (MCBD), Asst. Ch. Engr., Indus. Engr., Pressuretube, Inc., 609 W. 134th St., New York 31; *for mail,* 3354 Radcliff Ave., Bronx 67, N.Y.
Ferrary, Ferdinand F. (J'37) (LM), Mech. Engr., Ch. of Layout & Design, Ferrary Mar. Repairs, 278 Pearl St., New York; *for mail,* 538 E. 37th St., Brooklyn, N.Y.
Ferré, Luis Alberto ('40) (BCK), V.P., Charge Prod., Porto Rico Iron Works, Inc., Real St., Playa Ponce, P.R.
Ferretti, Alfred John ('17; '24; '30) (BFK), Prof. Mech. Engrg., Northeastern Univ., 360 Huntington Ave., Boston 15, Mass.
Ferris, Charles E. ('04; H'42), Dean of Engrg., Univ. of Tenn.; *for mail,* 2551 Kingston Pike, Knoxville, Tenn.
Ferris, Edwin Alden ('24; '42) (SFKC), Asst. Mgr., Charge of Serv., Serv. & Erection Dept., Combustion Engrg. Co., Inc., 200 Madison Ave., New York 16, N.Y.; *for mail,* 109 Hobart St., Ridgefield Park, N.J.
Ferris, Howard E. (J'39) (EFCLS), V.P., Charge Operas., S. Atlantic Gas Co., 114 Barnard St., Savannah, Ga.

Fitzsimmons, Joseph Harold (J'33) (SKY), Design Engr., Fed. Shipbldg. & Dry Dock Co., 744 Broad St., Newark, N.J.; *for mail,* 1181 Sheepshead Bay Rd., Brooklyn, N.Y.

Fitzsimmons, Saml. D. ('24), Ft. Myers, Fla.

Fixman, Carl M. (J'34) (EKSB), Mech. Engr., Public Works Div., Naval Shipyard, Mare Island; *for mail,* 927 Route Blvd., Albany 6, Calif.

Flack, Alonzo ('15; '35) (CDLM), Chmn., Treas., Mgmt. Counselor, Emerson Engrs., 30 Rockefeller Plaza, New York 20, N.Y.

Flad, Edward ('91) (O), Cons. Engr., Mem. Miss. River Comm., 828 U.S. Court House, St. Louis 1, Mo.

Flagg, Chas. N., Jr. ('15), Pres., C. N. Flagg & Co. Inc., 79 Griswold St., Meriden, Conn.

Flagge, Andrew (J'46) (JLM), Box 5651, Route 2, Des Plaines, Ill.

Flagle, Charles Denhard (J'40) (ABC), Design Engr., Westinghouse Elec. Corp., Lester, Pa.

Flaherty, Robert (J'41) (GJN), Design Engr., Miller Ptg. Mchy. Co., 1117 Reedsdale St., Pittsburgh 12; *for mail,* 49 Riverside Gardens, Pittsburgh 2, Pa.

Flanagan, James Henry (J'44) (AJECM), Lt. (j.g.), U.S.N.R.; *for mail,* 12 Lambert Rd., Belmont 78, Mass.

Flanagan, Robert G. (J'38), Tennant Co., 2905 Gulf Bldg., Houston, Tex.

Flanagan, Walter N. ('17; '20; '30) (JSFCED), Engrg. Consultant, Carnegie-Ill. Steel Corp., Carnegie Bldg., Pittsburgh 30, Pa.

Flanders, Ralph Edward ('08; '14; F'36) (NCR BML), *Manager,* '26-'29, *Vice-President,* '29-'31, *President,* '35; *Worcester Reed Warner Medallist,* '34; Pres. on Leave, Jones & Lamson Mch. Co. & Bryant Chucking Grinder Co.; *for mail,* Box 477, Springfield, Vt.

Flar, Henry (J'43) (MCSLDJ), Expediting Engr., M. W. Kellogg Co., Foot of Danforth Ave.; *for mail,* 307 Chapel Ave., Jersey City 5, N.J.

Flateboe, E. I. ('14; '35), Gen. Mgr., Sumner Iron Works, Box 1006, Everett, Wash.

Flater, Harold ('22), Works Mgr., Internatl. Harvester Co., Norrköping, Sweden.

Flather, Frederick Arthur ('92) (TCMHSD), Treas.-Mgr., Boott Mills, Milk St., Boston; *for mail,* Mansur St., Lowell, Mass.

Flatow, Walter W. (J'45) (CJLMN), 914—1st Ave., Spokane 6, Wash.

Flavin, Edward J. (J'36) (KMB), Mech. Engr., Griscom-Russell Co., 285 Madison Ave., New York 17, N.Y.

Flaws, David Banks (J'37) (LJ), Planning Engr., Lummus Co., 420 Lexington Ave., New York 17; *for mail,* 1514 Metropolitan Ave., New York 62, N.Y.

Fleet, Samuel L. ('19; '35) (O), Engr., Estimator, S. L. Fleet Co., Inc., 51 Madison Ave., New York 10, N.Y.

Fleischer, Irving (J'44), Hyd. Engr., Greer Hydraulics, Inc., 1776 Broadway; *for mail,* 108 S. Village Ave., Rockville Centre, N.Y.

Fleischer, Thomas (J'42) (JSM), Lt. (j.g.), U.S.N.R., Engrg. Officer, LSM-303, F.P.O., New York, N.Y.; *for mail,* 1141 N. New St., Bethlehem, Pa.

Fleischmann, Walter Ludwig ('44) (JBSZCK), Metal. Engr., Turbine Generator Engrg. Div., Gen. Elec. Co., 1 River Rd., Schenectady 5, N.Y.

Fleisher, Walter L. (J'42) (BFKOTY), Pres., Air & Refrigeration Corp., 475—5th Ave., New York 17, N.Y.

Fleming, Sir Arthur P. M. ('28), Dir., Metro.-Vickers Elec. Co., Ltd., Trafford Park, Manchester 17, England.

Fleming, Burritt Gray ('31; '45) (ABCDFH), Field Engr., Wright Aero. Co., Cincinnati 15; *for mail,* 6618 Elm St., Mariemont, Cincinnati 27, Ohio.

Fleming, David H., Jr. (J'41) (BJM), Devel. Engr., Linde Air Products Co., 646 Freylinghuysen Ave., Newark; *for mail,* 31 E. Highland Ave., Orange, N.J.

Fleming, John Taylor (J'28) (CJM), Asst. to Eng. Dir., John Brown & Co. Ltd., Engrs. & Shipbldrs., Clydebank, Glasgow; *for mail,* 15 Westbourne Dr., Bearsden, Scotland.

Fleming, Laurence Trent ('20; '35) (ROCB), Chief Rail Branch, Research & Devel. Div., Office of Chief of Trans., War Dept., The Pentagon, Washington 25, D.C.; *for mail,* 105 La Fonda Ave., Box 86, Route 1, Santa Cruz, Calif.

Fleming, Robert Martin ('43) (SKFC), Power Dept. Head, Diamond Alkali Co., Painesville, Ohio.

Fleming, Wills M. ('05; '09) (HM), Ch. Engr., Reciprocating Pump Engrg. Div., Worthington Pump & Mchy. Corp., Harrison; *for mail,* 51 Bennett Ave., Arlington, N.J.

Fleser, Russell Harrison, Jr. (J'42) (ABHMSK), Aircraft Draftsman, Douglas Aircraft Co., Inc., Lakewood & Carson, Long Beach; *for mail,* 440 N. Citras Ave., Los Angeles 36, Calif.

Flesher, Marion George ('28; '35) (SFEKJO), Engr., Westinghouse Elec. Corp., 20 N. Wacker Dr., Chicago; *for mail,* 11721 Longwood Dr., Chicago 43, Ill.

Fletcher, Edwin Hubert (J'45) (ENMJHC), Engrg. Draftsman, Bethlehem Steel Co., 3075 Richmond Terrace, Staten Island 3; *for mail,* 52 Delafield Ave., Staten Island 1, N.Y.

Fletcher, James ('24), Engr., Babcock & Wilcox Co., Barberton, Ohio.

Fletcher, James Loren ('32; '41) (CKBYJM), Dir. of Devel., Carrier Corp., 300 S. Geddes St., Syracuse 1, N.Y.

Fletcher, Leonard J. ('41) (CEM), Trng. Library, Bldg. X (Librarian), Caterpillar Tractor Co., Peoria 8, Ill.

Fletcher, Northrop Rogers ('24; '30; '35) (EFJ NOS), Mech. Engr., Asst. Diesel Consultant, Ebasco Services Inc., Rm. 1100, 2 Rector St., New York 6, N.Y.

Fletcher, Ralph Leslie ('26) (CFSK), V.P., Providence Gas Co., 100 Weybosset St., Providence 1, R.I.

Fletcher, Thomas Frederic ('45) (FKS), Supvg. Engr., Cía. Swift de La Plata, Puerto La Plata, F.C.S., Argentina, S.A.

Flickinger, John Hodgdon (J'46) (CM), Mfg. Engr., Gen. Elec. Co., 6901 Elmwood Ave., Philadelphia; *for mail,* 814 N. 63rd St., Philadelphia 31, Pa.

Fliendner, Angus T. ('38) (NBMJH), Design Engr., Cleveland Tractor Div., Oliver Corp., 19300 Euclid Ave., Cleveland; *for mail,* Erie Rd., Willoughby, Ohio.

Flink, Axel A. (J'35) (CMO), Cons. Engr., Prod. Mgmt. Engrg. Associates, Inc., Rm. 375, Russ Bldg., San Francisco; *for mail,* 2708 Via Campesina, Palos Verdes Estates, Calif.

Flinn, A. V. (DHMBFG), Managing Dir., Adamson-Alliance Co., 165 Fenchurch St., London, E.C. 3; *for mail,* Doveleys Rd., Pendleton, Manchester, England.

Flinn, William Stuart (J'45), Engrg. Research & Devel. Dept., Elliott Co., Jeannette; *for mail,* 25 Hazel Dr., Pittsburgh 16, Pa.

Flinner, A. O. ('29; '35; '35) (EFS), Assoc. Prof. Mech. Engrg., Kan. State College of Agric. & Applied Sci., Manhattan, Kan.

Flint, Amos Henry ('42) (EGLOSZ), Ch. Engr., Corn Products Refining Co., 333 N. Michigan Ave., Chicago 1, Ill.

Flint, Charles Kimball ('27) (CS), V.P., Gen. Mgr., Kodak Park Works, Eastman Kodak Co., Rochester 13, N.Y.

Flint, Eugene Marcus ('41) (GCMY), Maint. Engr., Rand McNally & Co., 536 S. Clark St., Chicago 5; *for mail,* 1931 S. 10th Ave., Maywood, Ill.

Flint, Thomas (J'40) (NBJMDG), Ch. Engr., J. W. Greer Co., 119 Windsor St., Cambridge; *for mail,* Simon Willard Rd., Concord, Mass.

Flitner, David Perkins (J'45), U.S. Navy; Greenville, N.H.

Flood, Henry, Jr. ('16; '35), Apt. 407, 36 Riverside Ave., Red Bank, N.J.

Floodeen, Eddy ('24; '35) (ONMKBJ), Cons. Engr., 1504 Smith Tower, Seattle 4, Wash.

Floor, Erik ('45) (HOS), Erik Floor & Associates, 139 N. Clark St., Chicago 2, Ill.

Floor, Urban (J'45) (HBEANS), Engr., Woodward Governor Co., 5001 N. 2nd Ave., Rockford, Ill.

Floreen, Edward Dore (J'41) (MCNKDF), Design Engr., Rudy Furnace Co.; *for mail,* 106 Green, Dowagiac, Mich.

Florek, Ralph Stephen (J'41) (CMY), Ch. Engr., Moore Enameling & Mfg. Co., West Lafayette, Ohio.

Florin, Urban Albert (J'43) (ASJBHK), Engrg. Apprentice, Indus. Engrg. Dept., E. J. Brach & Sons, 4600 W. Kinzie, Chicago; *for mail,* 3912 N. Kenneth, Chicago 41, Ill.

Florschutz, Fritz Edmund ('44) (NJBCMO), Chief, Drawing Office, Switch Gear Div., Westinghouse Elec. Corp., East Pittsburgh; *for mail,* 12 Hawthorne Rd., Pittsburgh 21, Pa.

Flounders, James McCay (J'41) (YCM), Sales Engr., B. F. Goodrich Co., 500 S. Main St., Akron, Ohio.

Flower, Ad ('24) (SFKECO), Sales Mgr., New York Office, Edge Moor Iron Works, Inc., 7204 Empire State Bldg., New York 1, N.Y.; *for mail,* 819 N. Harrison St., Wilmington 32, Del.

Flowers, H. Fort ('39) (DMR), Pres., Gen. Mgr., Differential Steel Car Co., Findlay, Ohio.

Flygare, Carl G., Jr. (J'41), 116 Forest St., Worcester 5, Mass.

Flyke, Milton Joseph (J'45) (SNKMCH), 606 S. Scoville Ave., Oak Park, Ill.

Flynn, Charles Andrew ('16) (BCDMOZ), V.P., Treas., Flynn-Hill Elevator Corp., 6 Howard St., New York 13, N.Y.

Flynn, Edward David ('38) (LHCY), Ch. Engr., Oliver United Filters, Inc., 2900 Glascock St., Oakland 1, Calif.

Flynn, John Bernard ('44) (BCHJMY), Exper. Engr., Fisher Body-Ternstedt Div., Gen. Motors Corp., 6307 W. Fort St., Detroit 9; *for mail,* 2253 Gladstone Ave., Detroit 6, Mich.

Flynn, John V. (J'40) (CFS), 49 Dixie Dr., Penns Grove, N.J.

Flynn, Michael Henry ('13) (CMNDB), Methods & Layout Engr., Royal Typewriter Co., Inc., 150 New Park Ave., Hartford 6; *for mail,* 113 Whitney St., Hartford 5, Conn.

Flynn, Roland W. ('41) (EJLSBM), Div. Lub. Engr., Gulf Oil Corp., 17 Battery Pl., New York 4, N.Y.

Flythe, John Thomas, Jr. (J'43) (JNMC), Jr. Design Engr., Richmond Engrg. Co., Inc., 7th & Hospital Sts., Richmond 5; *for mail,* 2703 Chamberlayne Ave., Richmond 22, Va.

Foard, Castie W. ('36) (BAZM), Physicist, Devel. Dept., Camera Works, Eastman Kodak Co., 333 State St., Rochester 4, N.Y.

Fobian, George Willard (J'42), Design Engr., Lister-Blackstone, Inc., 1706 S. 68th, West Allis; *for mail,* 129 N. 91st Pl., Milwaukee, Wis.

Fobian, Robert John (J'40) (HMCAEL), Mech. Engr., Devel. Work, Oilgear Co., 1403 W. Bruce St., Milwaukee 4; *for mail,* 1733 S. 76th St., West Allis 14, Wis.

Fodor, Nicholas ('24; '30) (ERHAO), Pres., Ch. Engr., Diesel Engrg. & Mfg. Corp., 200 N. Laflin St., Chicago 7; *for mail,* 835 Greenwood Ave., Wilmette, Ill.

Foell, Charles Francis (J'41) (ERS), Tech. Writer, Editor, Socony-Vacuum Oil Co., Inc., 26 Broadway, New York 4; *for mail,* 32-18 Bell Blvd., Bayside, N.Y.

Fogarty, Wm. Bailey ('45), Comdr., U.S.N., Retired; 624 Lincoln Ave., Cincinnati, Ohio.

Fogel, Jerome J. (J'40) (MCJD), Prod. Engr., Automotive Specialty Co., Inc., 382-386 Jefferson St., Brooklyn 6; *for mail,* 105 Buckingham Rd., Brooklyn 26, N.Y.

Fogelson, Emile ('27) (NAJDSY), Charge Mch. Design, Prod. Methods, Inc., 48 E. 43rd St., New York 17; *for mail,* 410 Central Pk. W., New York 25, N.Y.

Fogelsonger, Robert B. (J'40) (MSC), 100 Maple St., Clarence Center, N.Y.

Fogg, Oscar H. ('07; '13), Chmn. of Exec. Com., Consltd. Edison Co. of N.Y., Inc., 4 Irving Pl., New York 3, N.Y.

Fogg, William Raymond ('21) (OL), Arch. Engr., Partner, Ballinger Co., 105 S. 12th St., Philadelphia 7; *for mail,* 41 W. Stratford Ave., Lansdowne, Pa.

Fogler, Ben Baker ('12; '18; '22) (OLT), Sr. Engr., Arthur D. Little, Inc., 30 Memorial Dr., Cambridge 42, Mass.

Fogwell, J. Wray (J'40) (ABJ), Mech. Engr., Cuno Engrg. Corp., 80 S. Vine St., Meriden; *for mail,* 47 Berkley Court, Southington, Conn.

Foley, Edward Michael (J'41) (SLKE), Lt. (j.g.), U.S.S. *Midway,* F.P.O., New York, N.Y.; *for mail,* 3443 N.E. 35th Ave., Portland, Ore.

Foley, Glenroy B. ('28; '40) (C), Mech. Engr., Bur. of Ships, Navy Dept., Washington, D.C.; *for mail,* Box 104, Ridlonville, Me.

Foley, Jas. A. ('29), Mech. Bridge Engr., Hudson County Engrg. Dept., Court House; *for mail,* 439 Fairmont Ave., Jersey City, N.J.

Foley, Matthew J. (J'40), Jr. Mech. Engr., with W. F. Tuttle, Works Engr., Am. Rolling Mill Co.; *for mail,* 2367 Tytus Ave., Middletown, Ohio.

Foley, Raymond B. ('45) (DHKS), Supvr., Dust Collector Research, Am. Blower Corp., Detroit 32, Mich.

Foley, W. S. ('37) (HECJ), Asst. Engr., Distribution & Transmission, Bur. of Water, City of Philadelphia, 829 City Hall Annex, Philadelphia; *for mail,* 750 Adams Ave., Philadelphia 24, Pa.

Foley, Walter Joseph ('10; '23) (HDO), Dredging Engr., Stand. Dredging Corp., 800 Central Bldg., Los Angeles 14, Calif.

Follari, Salvatore (J'46), Petroleum Heat & Power Co., Stamford, Conn.

Folmsbee, Clyde Henry ('39) (RCBMKH), Asst. Mech. Engr., Am. Car & Fdy. Co., Oak & 9th Sts., Berwick; *for mail,* 344 E. Main St., Bloomsburg, Pa.

Folsom, Richard Gilman ('29; '40) (HABZ), Assoc. Prof. Mech. Engrg., Univ. of Calif., Berkeley 4, Calif.

Foltz, Raymond D. ('21; '25; '35) (CFJKMS), Pres., M. H. Detrick Co., 21 West St., New York 6, N.Y.

Folz, Joseph James (J'40) (LKSFBC), Process Engr. (Project), E. I. du Pont de Nemours Co., 9498 Nemours Bldg., Wilmington, Del.

Fomilyant, Anatol A. ('45) (CBJLMH), Partner, All Am. Fabricators, 2201 E. 51st St., Los Angeles 11; *for mail,* 3554 Mountain View Ave., Pasadena 8, Calif.

Fonda, Frederick Anthony (J'43) (CFS), Lt. (j.g.), U.S.N.R., U.S.S. *Greene*, F.P.O., San Francisco, Calif.
Foody, John Joseph ('44) (SEKHCO), Mech. Engr., Ebasco Services Inc., 2 Rector St., New York 6; *for mail*, 3321 Bruckner Blvd., New York 61, N.Y.
Foord, James L. ('15) (R), R.D. 5, Canoga Rd., Auburn, N.Y.
Foote, Avery George ('43), Regional Engr., Frigidaire Div., Gen. Motors Corp., 1250—53rd St., Oakland 8; *for mail*, 365 Vermont Ave., Berkeley 7, Calif.

Genung, Burton Edward (J'40) (AM), 983 Clayton, San Francisco, Calif.
George, Abraham (J'40) (MAJBN), 1st Lt., Army Air Forces, Engrg. Officer; 188 Daniel Low Terrace, Staten Island 1, N.Y.
George, Everett Dwaine (J'38) (NYHB), Sr. Mch. Designer, Goodyear Tire & Rubber Co., 1144 E. Market St., Akron; *for mail,* 2446 Chestnut Blvd., Cuyahoga Falls, Ohio.
George, Francis Xavier (J'34) (SKEBHN), Mar. Surveyor, Pillsbury & Martignoni, 220 Bush St., San Francisco 4; *for mail,* 2641 School St., Oakland 2, Calif.
George, Harry Frederick (J'44) (MNSKGB), Engrg. Draftsman, Combustion Engrg. Co. Inc.; *for mail,* 1202 Hanover, Chattanooga, Tenn.
George, Harvey Franklyn (J'45) (ABNKHJ), Stress Analyst, Lark Div., Fairchild Airplane & Eng. Corp., 184-10 Jamaica Ave., Jamaica; *for mail,* 191-54—112th Rd., St. Albans 12, N.Y.
George, Leonard Beattie ('25; '35) (ES), C. & R. Div., Mar. Dept., Socony-Vacuum Oil Co., Inc., 26 Broadway, New York 4; *for mail,* 14-A Castleton Pk., Staten Island 1, N.Y.
George, Vincent C. ('31) (BKSEF), Physics Instr., Los Angeles City College, 855 N. Vermont; *for mail,* 866 N. Edgemont, Los Angeles 27, Calif.
Georger, Francis Augustus, Jr. (J'45), Plant Engr., Precision Metalsmiths Inc., 6511 Cedar Ave., Cleveland, Ohio.
Georger, Roland Sylvester ('45) (NBCHDG), Partner, Reimann & Georger, Ellicott Sq., Buffalo 3; *for mail,* 119 Mt. Vernon Rd., Snyder 21, N.Y.
Georgian, John C. (J'40) (BESN), Engr., Charge of Torsional Vibration Analysis, Nordberg Mfg. Co., 3073 S. Chase Ave., Milwaukee 7; *for mail,* Box 656, R.F.D. 5, Waukesha, Wis.
Gerber, Samuel R. ('41) (CJM), Pres., Gen. Mgr., Kent Metal Mfg. Co., Inc., 490 Johnson Ave., Brooklyn 6, N.Y.
Gerdes, Henry Albert (J'42) (SEKFO), Lt., U.S.N.R., Ship Supt., Naval Shipyard, Philadelphia 12, Pa.; *for mail,* 531 Fairway Rd., Ridgewood, N.J.
Gerdes, Wayne R. (J'41) (RMS), Gen. Elec. Co., 409 S. 17th St., Omaha 2, Neb.
Gerding, John E. (J'41) (CDM), 2057 Cardiff Rd., Schenectady 7, N.Y.
Gerhard, Sidney (J'45) (AZCM), Cpl., Devel. Engr., Supersonic Wind Tunnels Lab., Aberdeen Proving Ground, Md.; *for mail,* 1405—42nd St., Brooklyn 19, N.Y.
Gerla, Mrs. Miriam Kleeger (J'44) (HKNBAY), Devel. Engr., Shirgun Corp., 136 W. 52nd St., New York 19; *for mail,* 936—55th St., Brooklyn 19, N.Y.
Gerla, Morton (J'37) (NBJHOD), Project Engr., Ord. Design Supvr., Shirgun Corp., 136 W. 52nd St. New York 19; *for mail,* 936—55th St., Brooklyn 19, N.Y.
German, Abraham Johannes ('21) (SFKHCE), Ch. Engr. of Power Plants, Scovill Mfg. Co., Mill St., Waterbury 91; *for mail,* 22 Adelaide, Waterbury 61, Conn.
German, John George (J'44) (RSNBCD), Asst. to M.M., Hillyard Depot, Great No. Ry. Co.; *for mail,* E. 2727 Queen Ave., Spokane 14, Wash.
Germer, Fred W. (J'43) (MNBJC), Pres., Gen. Mgr., Ch. Engr., Advanced Aircraft, Inc., 33-22 Northern Blvd.; *for mail,* 43-41—45th St., Long Island City 1, N.Y.
Germond, Earl Goerke (J'40) (KCDJSN), Plant Engr., Natl. Carbide Corp., Ivanhoe, Va.
Germond, Robert Work (J'45) (BCJ), Engr., Charge of Research & Sales, R. P. Kincheloe Co., 1411 Fannin, Houston; *for mail,* Apt. 19, 1321 S. Main St., Houston 2, Tex.
Gero, George (J'42) (AHK), Pvt., Btry. E, 34th Bn., 8th Regt., Field Arty. Replacement Trng. Center, Ft. Sill, Okla.
Gerritzen, Howard Kenneth (J'43) (ACFHMS), Capt., Army Air Forces, Project Engr., Propeller Lab., Wright Field, Dayton; *for mail,* 1628 San Rae Dr., Dayton 9, Ohio.
Gershberg, Joseph ('32) (FHS), Div. Engr., Mech. Testing, Brooklyn Edison Co., 1 Hudson Ave., Brooklyn, N.Y.
Gershenow, Harold Joseph (J'44), Mass. Inst. of Tech.; *for mail,* Apt. 1, Drayton Hall, 48 Boylston St., Cambridge, Mass.
Gersoni, Louis J. ('41) (SFLMOD), Ch. Engr., Hygrade Food Products Corp., 30 Church St., New York, N.Y.
Gerstmyer, Robert George (J'43) (CMODYZ), Graduate Student, Wharton Graduate Sch., Univ. of Pa., Philadelphia, Pa.; *for mail,* 1510 Shadyside Rd., Baltimore 18, Md.
Gerstung, Harry Otto (J'43) (SAC), Steam Field Engr., Westinghouse Elec. Corp., 20 N. Wacker Dr., Chicago 6; *for mail,* 1819 W. Morse Ave., Chicago 26, Ill.
Gerstung, Harry Sinclair (J'41) (ESF), Lt. (j.g.), U.S.N., Naval Engrg. Exper. Sta., Annapolis, Md.
Gerzetich, Michael Augustine ('45) (FKS), Boiler Rm., Commonwealth Edison Co., Box 149, Pekin, Ill.
Gesell, Wm. H. ('18; '21; '35) (C), V.P., Lehn & Fink Products Corp., Bloomfield, N.J.
Gess, Louis ('28; '36) (HZB), Brown Instrument Co., Wayne & Roberts Ave., Philadelphia 44, Pa.
Gessling, George Fisher (J'39) (KL), Lt. (j.g.), U.S.N.R., Repair & Maint. Officer, Stand. Landing Craft Unit 62, F.P.O., San Francisco; *for mail,* 55 Kenyon Ave., Berkeley, Calif.
Gessner, Egon Fritz (J'41) (JMS), Ensign, U.S.N.R., 1627 Massachusetts Ave., Cambridge, Mass.
Gessow, Irving David (J'45) (YBKJTA), Matls. Engr., Consultant, Code 631, Bur. of Ships, Navy Dept., Washington, D.C.
Gethen, George S. ('43) (SFK), Sr. Engr., Philadelphia Elec. Co., 900 Sansom St., Philadelphia 5, Pa.; *for mail,* 1106 Belmont Ave., Collingswood, N.J.
Getsug, Bertram ('34; '45) (JSE), Mech. Engr., Naval Air Trng. Bases, Pub. Works Dept., Bldg. 45; *for mail,* 1906 E. Bobe St., Pensacola, Fla.
Gettinger, Leonard A. (J'37) (FLS), Mech. Engr., Bailey Meter Co., 8527 Rosalie Ave., Brentwood, St. Louis, Mo.
Getz, Horace Eshelman, Jr. (J'45) (KHNZL), Jr. Mech. Engr., Field Research Dept., Magnolia Petroleum Co., Box 900, Dallas 1; *for mail,* 226 S. Edgefield, Dallas 11, Tex.
Getzen, John Edwin ('25; '28; '35) (CADMJS), Assoc. with Harry G. Mouat, 744 Martin Bldg., Birmingham 3, Ala.
Getzoff, Edward M. ('19; '25; '30) (AZNBYJ), Project Engr., Red Bank Div., Bendix Aviation Corp., Pearl St.; *for mail,* Conover Lane, R.F.D., Red Bank, N.J.
Geuss, Joseph Anthony (J'43) (NBHCLJ), Mch. Designer, Clearing Mch. Corp., 6499 W. 65th St., Chicago 38; *for mail,* 3203 Clinton Ave., Berwyn, Ill.
Gevirtz, Stanley Aaron (J'46), New York Univ., University Heights, New York; *for mail,* 388 Drew St., Brooklyn 8, N.Y.
Gevrenz, Theodore M. (J'39) (CELMRS), Ch. Engr., Indus. Oil Sales, Socony-Vacuum Oil Co., Inc., 230 Park Ave., New York 17, N.Y.
Geyer, Henry Elmer ('25; '32; '35) (OLHBCK), Constr., Maint. Engr., Pipe Line Dept., Stand. Oil Co. of Calif., Box 311, Pittsburg; *for mail,* 6449 Harwood Ave., Oakland 11, Calif.
Giacchino, George Edward (J'44) (BKS), 2512 Hillcrest Rd., Drexel Park, Pa.
Giampiccolo, James S. (J'41) (M), Aero. Engr., Grumman Aircraft Engrg. Corp., Bethpage; *for mail,* 3308 Wallace Ave., New York, N.Y.
Gianelloni, Vivian Joseph ('17; '19; '24) (CBSRKD), V.P., Punta Alegre Sugar Sales Co., Apartado 1938, Havana, Cuba.
Giauque, Robert E. (J'36) (KS), Pres., Roberts-Konrad, Inc., 90 West St., New York 6, N.Y.
Gibb, John Collins ('44) (ERSFHK), Staff Engr., Lub. Dept., Tech. Div., Socony-Vacuum Oil Co., Inc., Rm. 1350, 26 Broadway, New York 4, N.Y.
Gibbons, Edward J. (J'42) (KLM), Camramatic Corp., New York; *for mail,* 1153 Grand Concourse, Bronx, N.Y.
Gibbons, James William ('30) (BCJ), Retired; 118-36—191st St., St. Albans 12, N.Y.
Gibbons, Joseph Butler (J'45) (MDCN), Test Engr., Gen. Elec. Co., Schenectady; *for mail,* 285 Lincoln Pl., Brooklyn, N.Y.
Gibbons, Michael Joseph ('17) (CDKO), Owner, M. J. Gibbons Supply Co., 601-31 E. Monument Ave., Dayton; *for mail,* 116 W. Thruston, Dayton 9, Ohio.
Gibbons, Philip Lake (J'41) (MNJSCG), Mfg. Planning Engr., West. Elec. Co., Inc., 100 Central Ave., Kearny; *for mail,* 24 Springfield Ave., Cranford, N.J.
Gibbs, Francis Orland (J'34) (CM), Gibbs Mch. Co., 1023 W. Lee St.; *for mail,* 403 Aberdeen Terrace, Greensboro, N.C.
Gibbs, Lloyd Tolbert ('45) (BEHJS), Owner, Mgr., Lloyd T. Gibbs Co., Petroleum Bldg., Tulsa 3, Okla.
Gibbs, Maxwell ('44) (OCMBLN), Cons. Engr., 1927 W. 6th St., Los Angeles 5, Calif.
Gibbs, Robert Glenn (J'38) (CSA), Field Engr., Gen. Elec. Co., 235 Montgomery St., San Francisco 6, Calif.
Gibbs, Russell Everett ('31; '35) (SEFKAJ), Head, Dept. of Mech. Engrg., Mont. State College, Bozeman, Mont.
Gibillini, Emilio Paul (J'45) (CHM), Jr. Design Engr., Pelton Water Wheel Co., 2929—19th St.; *for mail,* 1471 Francisco St., San Francisco, Calif.
Gibney, James Joseph, Jr. (J'45) (SHBNR), Engr., Turbine Control Sec., Gen. Elec. Co., 1 River Rd., Schenectady; *for mail,* 907 Mason St., Schenectady 8, N.Y.
Gibson, Alfred E. ('32) (CDF), Pres., Wellman Engrg. Co., 7000 Central Ave., Cleveland 4, Ohio.
Gibson, Fred'k M. ('13) (FJKLS), Plant Engr., Am. Sugar Refining Co., 49 S. 2nd St., Brooklyn 11, N.Y.
Gibson, Frederick Montague, Jr. (J'40) (JMC), Ensign, U.S.N.R., M.E.I.U. 1, F.P.O., San Francisco, Calif.
Gibson, Geo. ('31; '40) (KLP), C. H. Leach Co., 117 Liberty St., New York, N.Y.; *for mail,* 110 Montclair Ave., Upper Montclair, N.J.
Gibson, Hamilton L. (J'31) (CS), Detroit Edison Co., 6603 W. Jefferson; *for mail,* 776 Beard Ave., Detroit 9, Mich.
Gibson, Harold D. (J'24) (BESONK), Mech. Engr., Equip. Devel., Stand. Oil Devel. Co., Box 37, Elizabeth, N.J.; *for mail,* 86 Crosshill St., Staten Island 1, N.Y.
Gibson, James (J'42) (WNCMHJ), Sr. Designer, Laighpark Works, T. White & Sons Ltd.; *for mail,* 39 Endrick Dr., Paisley, Scotland.
Gibson, James Edwin ('96; '01; '10) (CHO), Mgr., Engr., Commrs. of Pub. Works, 14 George St., Charleston A, S.C.
Gibson, John Stewart ('37) (SRJDN), Sales Engr., Drake Non Clinkering Furnace Block Co., 310 Renshaw Bldg., Pittsburgh 22, Pa.
Gibson, Norman R. ('27) (FHS), V.P., Buffalo Niagara Elec. Corp., 600 Elec. Bldg., Buffalo 3, N.Y.
Gibson, Robert MacDowell ('22; '35) (BELNRY), Engr., Koppers Co., Koppers Bldg., Pittsburgh 19, Pa.
Gibson, William A. ('44), Cons. Engr., 29-33 Wilson St., Redfern, Sydney, Australia.
Gibson, William Robert ('30) (SHKB), Owner, Mgr., Northwest Filter Co., 122 Elliott Ave. W., Seattle 99, Wash.
Gichner, Jacob Herman ('25; '32; '35) (CFJNRK), Comdr., U.S.N.R., Bur. of Ord., Navy Dept., Navy Bldg., Washington; *for mail,* 2101 New Hampshire Ave., N.W., Washington 9, D.C.
Giegengack, Augustus E. ('34) (GYC), Pub. Printer, Govt. Ptg. Office, N. Capitol & H Sts., Washington 25, D.C.
Giering, Percival L. ('45) (CO), Sr. Engr., Stevenson, Jordan & Harrison, 19 W. 44th St., New York 18; *for mail,* 60 Lakeville (Bates) Rd., Great Neck, N.Y.
Gies, Robert Paul (J'43), 8079 Whittaker Ave., Detroit 9, Mich.

Giesecke, Frederick Ernest ('36) (OGHBKZ), Cons. Engr., 276 E. Coll, New Braunfels, Tex.
Giesler, Jean V. ('23), Ch. Engr., Fulton Sylphon Co.; *for mail,* Box 104, Knoxville, Tenn.
Giffin, Daniel Anthony (J'43) (JOCBM), Student Test Engr., Gen. Elec. Co., 920 Western Ave., West Lynn, Mass.; *for mail,* 22 W. 18th Ave., Eugene, Ore.
Giffin, Leverett William (J'39) (ABM), Engr., Boeing Aircraft Co., Seattle, Wash.; *for mail,* 2040 S. Columbine, Denver 10, Colo.
Gifford, Albert James ('03;'31) (AHC), Treas., Leland-Gifford Co., Box 989, Worcester 1, Mass.
Gifford, Charles R. ('26) (DFKLSY), Owner, Firm of C. R. Gifford, 7310 Woodward Ave., Detroit 2, Mich.
Gifford, Robt. L. ('02), Pres., Ill. Engrg. Co., cor. 21st St. & Racine Ave., Chicago, Ill.; *for mail,* 1231 S. El Molino Ave., Pasadena, Calif.
Giguere, George Hector ('44) (SCOKLM), Ch. Engr., Smith, Hinchman & Grylls, 800 Marquette Bldg., Detroit; *for mail,* 2253 Burns, Detroit 14, Mich.
Gil, Ramón I. ('26; '33; '35) (SHKBAR), Assoc. Prof. Mech. Engrg., College of Agric. & Mech. Arts, Supt. Bldg. & Grounds, Univ. of P.R.; *for mail,* 114 Hostos, Mayaguez, P.R.
Gilbert, Carl L. (J'27) (CMS), Lt. Comdr., U.S.N.R., Navy 728, Box A, F.P.O., New York, N.Y.
Gilbert, Earl Clark, Jr. (J'45), 4726 Bloomington Ave. S., Minneapolis, Minn.
Gilbert, Edward (J'43) (BHKEMN), Jr. Engr., Westinghouse Elec. Corp., Lester P.O.; *for mail,* 1844 Nolan St., Philadelphia 38, Pa.
Gilbert, Ernest M. ('16) (SFKHO), Chmn. of Bd., Ch. Engr., Gilbert Associates, Inc., 412 Washington St., Reading 7, Pa.
Gilbert, Harold Maier (J'40) (MCA), Design Engr. on Modifications, Douglas Aircraft Co., Inc., Santa Monica; *for mail,* 855½ N. Alta Vista Blvd., Los Angeles 46, Calif.
Gilbert, James R., Jr. (J'39) (FKMCZS), 9005 Muskegon Ave., Chicago 17, Ill.
Gilbert, Kermit C. (J'31) (CSZ), 1028—43rd St., Belview Heights, Birmingham, Ala.
Gilbert, Nathan (J'41) (BNMHKS), Asst. Mech. Engr., Design Dept., N.Y. Naval Shipyard, Brooklyn; *for mail,* 15 Westminster Rd., Brooklyn 18, N.Y.
Gilbert, Norman Roland (J'38) (MCLBJZ), Mech. Engr., Univ. of Calif., Box 1663, Santa Fe, New Mex.
Gilbert, Russell Lowe (J'24) (BJKNSY), Mech. Engr., Taylor Elec. Mfg. Co., 625 Princess Ave.; *for mail,* 522 Piccadilly St., London, Ont., Can.
Gilbert, William Wayne (J'35) (MNLA), Assoc. Prof., Metal Processing Dept., Univ. of Mich., Ann Arbor, Mich.
Gilbertson, John Stewart, Jr. (J'44) (ASEB), Jr. Engr., Pratt & Whitney Aircraft Div., United Aircraft Corp., 400 S. Main St., East Hartford 8; *for mail,* 170 N. Beacon St., Hartford 5, Conn.
Gilbreth, Frederick M. (J'38) (CMD), Assoc. Engr., McKinsey & Co., 60 E. 42nd St., New York 17, N.Y.
Gilbreth, Mrs. Lillian Moller ('26; F'45) (CMO), Pres., Gilbreth, Inc., 30 The Crescent, Montclair, N.J.
Gilbreth, William Moller (J'36) (EF), Indus. Lub. Sales Engr., Gulf Oil Corp., 17 Battery Pl., New York; *for mail,* 12 Delmar Pl., Delmar, N.Y.
Gildea, David Jerome (J'45), Asst. Prof., Aero. Engrg. Dept., Pa. State College; *for mail,* 116 W. Hillcrest Ave., State College, Pa.
Giles, Charlie M. (J'43) (KBJM), Ch. Engr., Sweden Freezer Mfg. Co., 1140 W. 53rd St., Seattle 7; *for mail,* 2617—29th Ave. W., Seattle 99, Wash.
Giles, James Edward, Jr. (J'45) (AMCOJK), Asst. Project Engr., Jackson & Moreland, 31 St. James Ave., Boston 16; *for mail,* 44 Olive St., Newburyport, Mass.
Giles, Stuart (J'40) (MCE), Lt., U.S.N.R., Spec. Devices Div., Office of Research & Inventions, 610 H St., Washington 2, D.C.; *for mail,* 806 Greenwood Ave., Takoma 12, Md.
Gilg, Frank Xavier ('41) (FSWOE), Staff Engr., Babcock & Wilcox Co., 85 Liberty St., New York 6, N.Y.

Goodwin, Louis (J'41) (YMLCA), Jr. Engr., E. I. du Pont de Nemours & Co., Arlington; *for mail,* 745 West Side Ave., Jersey City, N.J.
Goodwin, Richer Mathieu (J'32) (EHJLS), Capt., U.S.A.; 4806 Springfield Ave., Philadelphia, Pa.
Goodwin, Walter Hardenbroecke (J'44) (BJS), Graduate Student, Calif. Inst. of Tech., Pasadena 4; *for mail,* 330 Lola Ave., Pasadena 8, Calif.
Goodyear, Howard Russell (J'37) (RKS), Capt., Field Arty., 736th Field Arty. Bn., Ft. Ord, Calif.
Goodzey, John Robert (J'40) (CJL), Engr., Anaconda Wire & Cable Co., California St., Sycamore 1; *for mail,* 2649 Haddon Ave., Chicago, Ill.
Goral, Edwin Bernard (J'44) (AKMNEJ), Mech. Engr., Natl. Advis. Com. for Aero., Langley Field; *for mail,* 53-C Elizabeth Rd., Hampton, Va.
Gorbaty, Arthur Mitchell (J'44) (BDM), 506—4th St., Niagara Falls, N.Y.
Gorder, Cyrus Garfield ('44), Asst. Boiler Rm. Engr., Commonwealth Edison Co., 3501 S. Pulaski Rd., Chicago 23, Ill.
Gordon, Allan Plummer (J'42) (CLMOS), 1115 Minnesota Ave., San Jose, Calif.
Gordon, Arthur (J'43) (NYMS), Technician, 5th Grade, 2881st Engrs., Army Ground Forces, A.P.O. 88, c/o Postmaster, San Francisco, Calif.; *for mail,* 216—9th Ave., Belmar, N.J.
Gordon, Charles William ('21; '25; '35) (KLFSRB), Ch. Engr., Drying Dept., Combustion Engrg. Co., Inc., 1319 N. Branch St., Chicago 22; *for mail,* 535 Oak St., Glen Ellyn, Ill.
Gordon, David ('27; '43) (LOFCKJ), Exec. V.P., David Gordon & Co., Inc., 29 Broadway, New York 6, N.Y.
Gordon, Edward David (J'41) (YNMJC), Staff Engr., Mech. Rubber Goods, Firestone Indus. Products, Firestone Pkwy., Akron 1; *for mail,* 890 Stadelman Ave., Akron 2, Ohio.
Gordon, Elliott Morton ('43) (CMJFGK), Exec. V.P., Gorham Mfg. Co., 333 Adelaide Ave., Providence 7, R.I.
Gordon, Eugene ('41) (SCFEH), Supt. of Power, Potomac Edison Co., 55 E. Washington St.; *for mail,* 528 Summit Ave., Hagerstown, Md.
Gordon, Hayden S. (J'41) (KAO), Engr., Radiation Lab., Univ. of Calif.; *for mail,* 2545 A Benvenue Ave., Berkeley 4, Calif.
Gordon, Henry Robert (J'41) (ABJ), 1st Lt., Corps of Engrs., 813th Engr. Aviation Bn., A.P.O. 986, Seattle, Wash.
Gordon, Myron B. ('20; '25) (ACMSJE), V.P., Charge of Operas., Fairchild Eng. & Airplane Corp., 30 Rockefeller Plaza, New York 20, N.Y.
Gordon, Peter Benjamin ('43) (SKLBZ), Treas., Engr., Wolff & Munier, Inc., 222 E. 41st St., New York, N.Y.
Gordon, Robert J. ('18; '26) (FSDKLM), Plant Engr., Walter Baker & Co., Inc., 1197 Washington St., Dorchester 24, Mass.
Gordon, Sidney (J'40) (BNAM), Gp. Leader, Mech. Design, Edo Aircraft Corp., College Point, L.I.; *for mail,* 187 Hicks St. (5-B), Brooklyn 2, N.Y.
Gordon, Vincent Joseph, Jr. (J'42) (MCSA), Jr. Mfg. Engr., Steam Div., Westinghouse Elec. Corp., Lester Branch P.O., Philadelphia 13; *for mail,* 718 Morgan Ave., Drexel Hill, Pa.
Gordy, George Baxter, Jr. ('44) (M), Mech. Engr., Arabian Am. Oil Co., 200 Bush St., San Francisco; *for mail,* 83 Pleasant St., San Francisco 8, Calif.
Gore, John Calvin (J'40) (SKCFEM), Power Engr., Post Products Div., Gen. Foods Corp., Battle Creek; *for mail,* 427 High St., Marshall, Mich.
Gore, Linn A. (J'34) (BAE), Dunlap, Kan.
Gore, Robert Thomas (J'45) (JKBZLF), Raw Matls. Engr., West. Elec. Co., Inc., 100 Central Ave., Kearny; *for mail,* Kings Highway, Middletown, N.J.
Gorham, John Milton ('42), V.P., Hartford Steam Boiler Inspc. & Ins. Co., 56 Prospect St., Hartford 2, Conn.
Gorlin, Boris (J'43) (MAB), Ch. Engr., Prod. Mgr., Burkaw Elec. Co., 105 E. 29th St., New York 16, N.Y.
Gorman, Joseph H. (J'39) (FKM), Motor Machinist's Mate, 3rd Class, Instr., Naval Trng. Sch., Richmond, Va.
Gormel, Ernest M. (J'32) (MNCKFE), Mech. Engr., Delco Appliance Div., Gen. Motors Corp., 391 Lyell Ave., Rochester; *for mail,* 260 Lincoln Ave., Rochester 11, N.Y.
Gormeley, James Francis (J'44), Pvt., 1st Class, Spec. Engrg. Det., Bks. Area, Oak Ridge, Tenn.; *for mail,* 570 Jersey Ave., Jersey City, N.J.
Gormley, John Joseph, Jr. (J'46) (KOS), Apt. 22, Barcroft Apts., 1303 S. Thomas St., Arlington, Va.
Gorrell, C. Woodrow (J'38), 146—9th Ave., South Charleston, W. Va.
Gorrie, Harvard H. (J'27) (BCJMZ), Design Engr., Bailey Meter Co., 1050 Ivanhoe Rd., Cleveland 12; *for mail,* 1155 Erieview Rd., Cleveland 21, Ohio.
Gorrie, John M. ('39) (CES), 356 Fuller Ave., S.E., Grand Rapids 6, Mich.
Gorton, Charles E. ('15; F'36), *Manager,* '25-'28, *Vice-President,* '28-'30; Chmn., Uniform Boiler Legislation, Am. Uniform Boiler Law Soc., 95 Liberty St., New York 6, N.Y.
Goryainoff, Alexis Nikolas (J'44) (BHK), Internatl. Gen. Elec. Co., Schenectady, N.Y.
Goryl, William Munder (J'46), 165 Hillside Ave., Hillside, N.J.
Goss, Robert J. (J'42) (LJMOSD), Mech. Engr., Maint., Am. Cyanamid Co., Warners St., Linden; *for mail,* 64 Pine Grove Terrace, Newark, N.J.
Goss, Stanley T. ('14), Pres., Goss & DeLeeuw Mch. Co., New Britain, Conn.
Gossman, Angelo Ludwig ('21; '25; '35), West Coast Mgr., Tile-Tex Co., 530 W. 6th St., Los Angeles 14; *for mail,* 1424 E. Mountain St., Glendale 7, Calif.
Gosting, Richard Ernest (J'42), Ensign, U.S.N.R., Kildare, Okla.
Gothberg, Edwin G. ('37; '40) (SEFCHK), Asst. Engr., Gas & Steam Dept., Pacific Gas & Elec. Co., 245 Market St., San Francisco 6; *for mail,* 2070—16th Ave., San Francisco 16, Calif.
Gotherman, Charles Warren ('42) (LDJKFO), Mech. Engr., N.J. Zinc Co., of Pa.; *for mail,* Residence Park, Palmerton, Pa.
Goto, Lawrence Harvey (J'45) (BNSMCH), Mech. Design Engr., Gen. Am. Trans. Corp., 209 W. Jackson Blvd., Chicago; *for mail,* 2913 N. Mulligan Ave., Chicago 34, Ill.
Gottesman, Arthur H. (J'44) (BZMCNA), Design Engr., Farrand Optical Co., Inc., 4401 Bronx Blvd., New York 66; *for mail,* 2200 Grand Ave., New York 53, N.Y.
Gottilla, Salvatore Charles (J'45) (BSYZCJ), 1779—46th St., Brooklyn 4, N.Y.
Gottlieb, Edward ('21; '27; '35), (CGO), Pat. Atty., 80 Wall St., New York 5, N.Y.
Gottsch, Donald Chris (J'42) (ASWOCF), Aviation Instr., Pilot, Bay Shore High Sch., 3rd Ave., Bay Shore; *for mail,* 74 W. Islip Rd., Babylon, L.I., N.Y.
Gotwals, Charles Scheetz ('20; '26) (CJM), Supt., Plant 1, SKF Industries, Inc., Front St. & Erie Ave., Philadelphia 34; *for mail,* 107 Cypress Ave., Jenkintown, Pa.
Gough, A. C. ('18) (GJM), Dir., Div. of Engrg., So. Branch, Univ. of Idaho, Pocatello, Idaho.
Gough, John Bernard ('24) (BHKDSL), Ch. Engr., Mead Corp., S. Paint St.; *for mail,* Box 93, Chillicothe, Ohio.
Gould, George Douglas (A'45) (GJCM), Engr., Chemco, Inc., New St., Glen Cove; *for mail,* Hickory Hill, Roslyn, L.I., N.Y.
Gould, Gerald B. ('31) (FSOE), Pres., Fuel Engrg. Co. of N.Y., Partner, Gould, Henderson & Brunjes, 215—4th Ave., New York 3, N.Y.
Gould, Jack U. ('46), Mech. Engr., Ferdinand Gutmann & Co., 3611—14th Ave., Brooklyn 18, N.Y.
Gould, Leo J. (J'28) (BNMFDH), Asst. Ch. Engr. of Constr., Bethlehem Steel Co.; *for mail,* 1803 Easton Ave., Bethlehem, Pa.
Gould, Norman J. ('00; '08), Pres., Goulds Pumps, Inc., Seneca Falls, N.Y.
Gould, Ralph L. ('44) (BCDJMN), Dir. Basic Research, Natl. Can Corp., 179 Hamilton Ave., Greenwich, Conn.; *for mail,* 164 Maple St., Springfield 5, Mass.
Gould, William Richard (J'42) (SNCH), Lt. (j.g.), U.S.N.R., Mchy. Inspc. Officer, c/o Supvr. of Shipbldg., U.S.N., San Pedro; *for mail,* 440 Coronado Ave., Long Beach 4, Calif.
Govan, John Hammond (J'36) (HLKJMD), Branch Mgr., Sales Engr., Can. Blower & Forge Co. Ltd., 1221 Bay St., Toronto 5, Ont., Can.
Gove, Norris Dickinson ('42), Engr., Westinghouse Elec. Corp., Lester; *for mail,* 847—11th Ave., Prospect Park, Pa.
Gow, Ralph Frederick ('26; '33; '35) (C), Works Mgr., Norton Co., 1 New Bond St., Worcester 6, Mass.
Gowdy, Allen Clair (J'43), 308 Standard Bldg., Atlanta 3, Ga.
Gowen, Raymond B. (J'40) (AJM), Lt., O-V(S), U.S.N.R., Naval Air Sta., Norfolk, Va.; *for mail,* 3619 Bowne St., Flushing, N.Y.
Gowling, Lawrence E. ('20; '35) (FKS), Mech. Engr., Compania Cubana de Electricidad, Box 1715, Monte 1, Havana, Cuba.
Graboski, Leo D. ('40) (EMR), Asst. Ch. Engr., Vulcan Iron Works, Box 570; *for mail,* 75 Graham Ave., Lee Park, Wilkes-Barre, Pa.
Grabowski, Edward John (J'44) (KLP), Chem. Engr., Hydrocarbon Research, Inc., 115 Broadway, New York; *for mail,* 2140 Chatterton Ave., New York 61, N.Y.
Grace, Charles Theron ('36; '45) (NBEJSO), Assoc. Prof. Mech. Engrg., Engrg. Hall, Univ. of New Mex., Albuquerque, New Mex.
Grace, John Francis ('15) (SKR), Condenser Engr., Worthington Pump & Mchy. Corp., 401 Worthington Ave., Harrison; *for mail,* 24 Alpine Pl., Arlington, N.J.
Grace, William A. ('27) (CEFKSY), Supt. of Maint., J. H. Williams & Co., 400 Vulcan St.; *for mail,* 251 Woodlawn Ave., Buffalo, N.Y.
Gracik, John Walter (J'38) (CAODHM), 1st Lt., Ord. Dept., Army Serv. Forces, Property Disposal Officer, Detroit Ord. Dist., 1832 Natl. Bank Bldg., Detroit 32, Mich.
Gradisar, Albin A. (J'39) (ABC), Devel. Engr., Spencer Lens Co., 19 Doat St.; *for mail,* 19 Oakmont Ave., Buffalo 15, N.Y.
Gradisar, Ivan A. (J'38) (ACJLM), Asst. Maint. Supvr., Columbia Chem. Co.; *for mail,* 40—14th St., Barberton, Ohio.
Grady, Charles B. ('14) (BDJKOS), Retired; Box 96, Skytop, Pa.
Grady, Edward Glennan ('41) (SWZMKC), Plant Engr., Masonite Corp., S. 4th Ave., Laurel, Miss.
Graef, Louis Fred ('18; '26; '35) (BDEH), Ch. Maint. Man, Rancho Los Amigos, Hondo, Calif.
Graesser, Carl H. ('38), V.P., Charge of Engrg. & Devel., Manning, Maxwell & Moore, Inc., 11 Elias St., Bridgeport 2, Conn.
Graesser, Elmer C. (J'37) (CJMNY), Plant Supt., Natl. Vulcanized Fibre Co., Maryland Ave. & Beech St., Wilmington 99, Del.
Graf, Frederick John ('31; '41) (CMZ), Asst. V.P., & Ch. Engr., Mass. Bonding & Ins. Co., 85 Water St., Boston 9; *for mail,* Doublet Hill Rd., Weston 93, Mass.

Graf, John C. ('13; '18; '35) (HYWK), Sales Mgr., Hyd. & Spec. Mchy. Div., William Sellers & Co., Inc., 1600 Hamilton St., Philadelphia 30; *for mail,* 705 E. Longshore Ave., Philadelphia 11, Pa.
Graf, John Richard (J'37) (NMJBHC), Mgr. Procurement, Stand. Vendors Div., Lehigh Fdys., Inc., Easton; *for mail,* 123 Roseland Ave., Philadelphia 11, Pa.
Graf, Julius Eicher ('39) (JBCM), Asst. Ch. Engr., Jones & Laughlin Steel Corp., 3rd Ave. & Ross St., Pittsburgh 30; *for mail,* 609 Perrysville Rd., West View 2, Pa.
Graf, Samuel Herman ('12; '20) (BJZO), *Manager, '43-'45, Director-at-Large, '45-'46;* Dir., Engrg. Exper. Sta., Ore. State College, Corvallis, Ore.
Graf, William, Jr. (J'29) (KLSCWR), 96 Summit Ave., Upper Montclair, N.J.
Graff, Paul Taylor ('44), Engr., Groton, Mass.
Graff, Truls Wiel (J'43) (BJKSHA), Elliott Co., Jeannette, Pa.
Graffeo, Alphonse J. (J'40) (BKS), 25 College Ave., Medford 55, Mass.
Graham, David P. (J'24), Engrg., Sales Devel., Peabody Engrg. Corp., 580—5th Ave., New York; *for mail,* 536 Livingston St., Westbury, L.I., N.Y.
Graham, Frederick C. (J'41) (MJOW), 1st Lt., U.S.A., Hdq., 140th Bomb Wing, P.R.O., Germany; *for mail,* 26 Bucklin, North Attleboro, Mass.
Graham, Glenn Robert (J'41) (BCJ), 1594 Wood Rd., Cleveland Heights, Ohio.
Graham, John Joseph (J'40) (FKS), 1st Lt., Sferics Div., Army Air Forces; 20020 Lomond Blvd., Shaker Heights 22, Ohio.
Graham, John Joseph (J'42) (MC), Mech. Design Engr., Gen. Elec. Co., 1 River Rd., Schenectady 5; *for mail,* 1735 Wendell Ave., Schenectady 8, N.Y.
Graham, John Stewart (J'44) (CMSZY), Ensign, U.S.N., YMS-124, F.P.O., San Francisco, Calif.; *for mail,* 16 Auburn St., Woburn, Mass.
Graham, Miss Lois (J'45) (AFK), Carrier Corp., Syracuse; *for mail,* 1704 S. Salina St., Syracuse 5, N.Y.
Graham, Mack Edward (J'41) (CMJ), Ensign, U.S.N.R., 9213 Annetta Ave., South Gate, Calif.
Graham, Paul S. ('43) (DCJMY), Switch Board Engrg., Mech. Engr., Westinghouse Elec. Corp., East Pittsburgh; *for mail,* 1058 Blackridge Rd., Pittsburgh 21, Pa.
Graham, Robert Fisher (J'43) (ACM), Lt. (j.g.), Instrument Maint., U.S.N., Bur. of Ships, Code 945, Navy Dept., Washington, D.C.; *for mail,* 5616 Pimlico Rd., Baltimore 9, Md.
Graham, Warren Wright ('18; '35) (SEFK), Sr. Mech. Engr., Plumbing & Htg., Fed. Pub. Housing Authority, Elec. Bldg., Ft. Worth 2; *for mail,* 611 W. 4th St., Ft. Worth 3, Tex.
Graham, William M. (J'33) (CLDOS), 9137 S. Ada St., Chicago 20, Ill.
Granata, A. J. (J'35) (CKL), Mgr., Applied Engrg. Dept., Pure Carbonic, Inc., 60 E. 42nd St., New York, N.Y.
Granberg, Bengt Rudolf ('41) (CHJLMN), Ch. Devel. Engr., Sundstrand Mch. Tool Co., Rockford, Ill.
Grandahl, Roland L. (J'41) (CMNJHB), Partner, Tool Engr., Grandahl Tool & Mch. Co., 1200 Park St., Hartford 6; *for mail,* 252 Sisson Ave., Hartford, Conn.
Grandin, Frederick ('46) (FMT), Application Engr., Westinghouse Elec. Corp., 1180 Raymond Blvd., Newark; *for mail,* 9 Theodore St., Wharton, N.J.
Grandinetti, John Russell ('45) (HBKOGC), Mech. Engr., Bur. of Engrg., Dept. of Pub. Works, City of Philadelphia, 1103 City Hall Annex, Philadelphia 7, Pa.
Granell, Edward Charles (J'45) (BJLMOZ), 285—18th Ave., Newark 3, N.J.
Granet, Irving (J'44), U.S. Army; 375 Rockaway Pkwy., Brooklyn 12, N.Y.
Graney, Robert William (J'39) (ARO), 4761 Rapid Run Pike, Cincinnati 5, Ohio.
Granger, Charles H. (A'34) (HCYL), V.P., Gen. Mgr., Waterbury Tool Div., Vickers, Inc., Waterbury 91; *for mail,* 199 Euclid Ave., Waterbury Conn.
Granger, Graham ('37) (FCERDS), Asst. V.P., East. Gas & Fuel Associates, 250 Stuart St., Boston 16, Mass.
Granger, John Maxwell (J'42) (ACM), 1266 Haro St., Vancouver, B.C., Can.
Granger, Thomas Scott (J'41) (NMJYG), Mech. Engr., RCA Victor Co. Ltd., 1001 Lenoir St., Montreal, Que., Can.
Granniss, Edward Robert ('39) (MGCD), Dir., Indus. Div., Natl. Conservation Bur., 60 John St., New York 7, N.Y.
Gransee, Harold Clifton (J'40) (SFEKA), Serv. Engr., Babcock & Wilcox Co., 85 Liberty St., New York 6, N.Y.
Grant, Arthur A. ('19) (CMP), 1745 Canal Bldg., New Orleans 12, La.
Grant, George Allen (J'43) (MCS), 920 Spruce St., Seattle, Wash.
Grant, H. C., Jr. (J'23), 165 Linwood Ave., Ridgewood, N.J.
Grant, Harold Robert (J'42) (BCM), Jr. Prod. Engr., Fluorescent Products Inc., 1240 S. Main St., Los Angeles; *for mail,* 751 S. Mariposa, Los Angeles 5, Calif.
Grant, Irving George ('31; '45) (SFHKED), Mech. Plant Betterment Engr., Ebasco Services Inc., 2 Rector St., New York 6, N.Y.
Grant, Ray Michael (J'45) (ELZ), Dist. Rep., Orr & Sembower, Inc., 228 N. La Salle St., Chicago 1; *for mail,* 11132 S. Edbrooke Ave., Chicago 28, Ill.
Grant, Taylor Banker ('23; '35) (CM), Specification Supvr., Bell Tel. Labs., Inc., 463 West St., New York 14; *for mail,* 99-41—65th Rd., Forest Hills, L.I., N.Y.
Grant, William Wulfing ('25; '35) (C), Dir., Marketing Research, Westinghouse Elec. Corp., 4th St.; *for mail,* 641 Glendale Blvd., Mansfield, Ohio.
Grapnel, Stefan Ludwik (J'43) (TZCN), Research Engr., Belding Heminway Co., Putnam, Conn.
Gras, Ranulf Worcester (J'43) (BAZNM), Staff Mem., Div. of Indus. Cooperation, Mass. Inst. of Tech., 77 Massachusetts Ave.; *for mail,* 48 Massachusetts Ave., Cambridge 39, Mass.
Graser, Theodore Nestor ('38) (CFSTZ), V.P., Treas., Cochrane Steam Specialty Co., 80 Federal St., Boston 10, Mass.
Grasse, Harold ('37; '43) (SOHE), Design Engr., Black & Veatch, Cons. Engrs., 4706 Broadway, Kansas City; *for mail,* 6444 Main St., Kansas City 5, Mo.
Grassi, Raymond Charles (J'41) (MJCNBD), Instr. in Mech. Engrg., 234 Mech. Bldg., Univ. of Calif., Berkeley 4, Calif.
Grassl, Robert N. (J'41) (ABNS), Design Engr., Westinghouse Elec. Corp., Lester Branch P.O.; *for mail,* 712—10th Ave., Prospect Park 13, Pa.
Gratch, Serge (J'44) (BKS), Instr., Dept. of Mech. Engrg., Univ. of Pa., Philadelphia 4, Pa.
Grauel, James Laverty ('43) (CLM), Ch. Engr., W. C. Hamilton & Sons, Box 48; *for mail,* Joshua Rd., Miquon, Pa.
Gravelle, Paul ('44) (FKS), Results Engr., Toledo Edison Co., Toledo; *for mail,* 2143 Central Grove Ave., Toledo 9, Ohio.
Gravenhorst-Brouwer, Otto C. (J'42) (H), Engr., Charge of Pump Tests, Pacific Gas & Elec. Co., 203 N. Sutter, Stockton, Calif.
Graves, Benjamin Parker ('23) (BHJMN), Dir. of Design, Brown & Sharpe Mfg. Co., Promenade St., Providence 1, R.I.
Graves, Colburn Rundio ('45) (CEFS), Supt. (Holder-Distribution), Brooklyn Union Gas Co., 176 Remsen St., Brooklyn 2; *for mail,* 134 Tullamore Rd., Garden City, L.I., N.Y.
Graves, Edwin Hawley (J'39) (CLWMDS), Asst. Gen. Mgr., Hummel-Ross Fibre Corp., Hopewell; *for mail,* 417 Libby Ave., Richmond, Va.
Graves, Frederick Emmons (J'43) (FLKZS), Devel. Engr., Surface Combustion Div., Webster Engrg. Co., 2375 Dorr St., Toledo 1, Ohio.
Graves, Lawrence Paul (J'45), 52 Circuit Park, Melrose 76, Mass.
Graves, Walter Joseph ('17) (BCDHOW), Retired; 16811 Ferguson Ave., Detroit 27, Mich.
Gravitz, Edward (J'44), U.S.N., 6103 Ellsworth St., Philadelphia, Pa.
Gray, Cecil ('43) (CRS), Mgr., Westinghouse Elec. Corp., 801 S. 5th St., Richmond 19, Va.
Gray, Charles J. (J'39) (RS), Draftsman, Atlantic Coast Line R.R. Co.; *for mail,* 1511 Rankin St., Wilmington, N.C.
Gray, David R. ('30; '36), Mech. Engr., Charge Maint., Diamond Match Co., Box 1483, Spokane, Wash.
Gray, Donald D. A. (J'42) (CHMNYG), Lt. Comdr., U.S.N.R., Office of Asst. to Indus. Mgr., U.S.N., Ferry Bldg., San Francisco, Calif.
Gray, Edward Greeley ('42) (YMBJ), Plastics Div., Gen. Elec. Co., 1 Plastics Ave.; *for mail,* 19 Brunswick St., Pittsfield, Mass.
Gray, Ellsworth S. ('37) (EFK), Prof. & Head, Dept. of Mech. Engrg., Sch. of Engrg., Univ. of Kan., 117 Marvin Hall, Lawrence, Kan.
Gray, Frank L., Jr. (J'43) (MYBADL), 807 W. Midland St., Bay City, Mich.
Gray, Frederick Ramsey ('22) (SE), Supvr., Westinghouse Elec. Internatl. Co., 40 Wall St., New York 5, N.Y.
Gray, George Francis ('42) (GNZB), V.P., Pratt & Gray Co., Inc., Box 127, Norwalk, Conn.
Gray, H. Liggett ('16; '25; '35) (AER), Asst. Mgr., Oakite Products, Inc., 22 Thames St., New York, N.Y.
Gray, Harland Alexander ('44) (ACJ), East. Dist. Engr., Cleveland Automatic Mch. Co., 15 Washington St., Newark, N.J.; *for mail,* Chestnut Hill, Norwalk, Conn.
Gray, Harry ('28) (BDH), Box 502, Morgan City, La.
Gray, Henry C. (J'17), Engrg. Dept., Falk Corp., Milwaukee; *for mail,* 4429 N. Cramer St., Milwaukee 11, Wis.
Gray, John Cameron (J'45), St. Lawrence Starch Co., Ltd., Port Credit, Ont., Can.
Gray, John Wilson ('95; '26) (CDAFMY), Retired; 226 Windermere Ave., Wayne, Pa.
Gray, Newenham Acton ('30) (BJL), Cons. Engr., 103 McIndoe St., Wausau, Wis.
Gray, Percy Scott (J'35) (CSZ), Mgr., H. S. Gray Co., 74 S. Queen St., Honolulu 2, T.H.
Gray, Robert Lee (J'41) (ECHSMD), Mar. Supt., Ashland Oil & Refining Co., 14th & Winchester, Ashland, Ky.
Gray, Thomas Collier ('39) (RMS), Comdr., U.S.N.R., Bur. of Ships, Navy Dept., Washington, D.C.
Gray, Wharton Kinsey ('28; '31; '35) (CDKLZ), Ch. Engr., Spreckels Sugar Co., 2 Pine St., San Francisco 11, Calif.
Gray, William Edward ('44), Box 264, High Point, N.C.
Gray, William Enoch ('36) (RBZSK), V.P., Engrg., Peerless Equip. Co., 332 S. Michigan Ave., Chicago 4, Ill.
Gray, William Thurston ('44) (BZKJH), Research Engr., Research & Devel. Dept., Corning Glass Works, Corning, N.Y.
Graybeal, Herbert Lee (J'40) (NBHJRW), Prin. Ord. Engr., Naval Shipyard, Mare Island; *for mail,* 58 B St., Vallejo, Calif.
Greacen, Walter, 3rd ('37) (SFKC), Mech. Engr., Charge Power Stas., N.Y. State Elec. & Gas Corp., 62 Henry St.; *for mail,* 37 Crestmont Rd., Binghamton, N.Y.
Greagan, John J. ('17; '21), Mgr., Allis-Chalmers Mfg. Co., 1303 1st Natl. Bldg., Birmingham 3, Ala.
Greanias, Gus George (J'43) (HAM), 242 E. Grand, Decatur 8, Ill.
Greaves, Donald Leonard, Jr. (J'41) (SFKOEB), Mech. Engr., Ebasco Services Inc., 2 Rector St., New York 7, N.Y.; *for mail,* 130 Prospect St., East Orange, N.J.
Greaves, Fred George, Sr. ('25; '35) (DKLWYZ), Sr. Partner, Ch. Engr., Fred G. Greaves Co., 502 Polson Bldg.; *for mail,* 2015—35th Ave. W., Seattle 4, Wash.
Grebe, John Josef ('30; '34) (AFLSZ), Dir., Physical Research Lab., Dow Chem. Co., Midland, Mich.
Greeley, Charles E. (J'37) (CEK), Mar. Engr., Merchant Mar.; Ada, Minn.
Green, Allen Percival ('44), Pres., A. P. Green Fire Brick Co.; *for mail,* 16 S. Jefferson Rd., Mexico, Mo.
Green, Andrew Shaw ('36; '46) (HBNEAJ), Supvr. of Design, Naval Arch., Office of Asst. to Indus. Mgr., U.S.N., Ferry Bldg., San Francisco 11; *for mail,* 612—37th St., Richmond, Calif.
Green, Arthur Brooks ('22) (CMWZ), Treas., Paprex Co., 284 Harris Ave., Needham 92, Mass.
Green, Ben H. ('21; '35) (CFS), Gen. Supt. Steam Plants, Cent. N.Y. Power Corp., Box 418; *for mail,* 228 E. 5th St., Oswego, N.Y.
Green, Boynton Morris ('21; '35) (NMJBL), *Student Award, '16;* Prof. Mech. Engrg., Stanford Univ.; *for mail,* 691 Salvatierra St., Stanford University, Calif.
Green, Charles E. (J'41) (CJS), Apt. 4J, New Hall Apts., 8309 Talbot St., Kew Gardens, L.I., N.Y.
Green, Charles Henry (J'45), Partner, Wm. F. Surgi Equip. Co., 1017 Magazine St., New Orleans 13, La.
Green, Clarence Raymond (J'37) (SFCZD), Jr. Engr., Detroit Edison Co., 2000—2nd Ave., Detroit 26; *for mail,* 325 Helen Ave., Trenton, Mich.
Green, Edward Orville (J'40) (AM), 3710 College Ave., Kansas City 3, Mo.
Green, Frank Benjamin Kitchener (J'43) (SLM), 528—5th St., Brooklyn 15, N.Y.
Green, Fred'k W. ('18) (BRS), Ch. Opera. Officer, St. Louis Southwest. Ry. Lines, 515 Cotton Belt Bldg., St. Louis, Mo.
Green, Heatley ('19), Pres., Automatic Products Co., 1145 W. Grand Blvd., Detroit, Mich.

Harris, Sydney Preston (J'37) (JMZ), Mech. Engr., Schick Inc., 45 Garden St., Stamford; *for mail,* 7 Phillips Lane, Darien, Noroton Heights, Conn.
Harris, W. Eugene (J'33) (OSCL), Mech. Engr., DeLeuw, Cather & Co., 20 N. Wacker Dr., Chicago 6; *for mail,* 1305 N. Monitor Ave., Chicago 51, Ill.
Harris, William B. D., Jr. (J'43) (ZMG), R. D. 2, Doylestown, Pa.
Harris, William John, Jr. ('13) (FJ), Indus. Fuel Engr., Laclede Gas Light Co., 1017 Olive St., St. Louis 1; *for mail,* Route 2, Valley Park, Mo.
Harris, Zachary Nick (J'43) (CMNAKJ), Jr. Mech. Engr., Goodyear Aircraft Corp., Akron; *for mail,* 924 N. Howard St., Akron 10, Ohio.
Harrison, Chas. Geo. ('24) (SF), Owner, Chas. G. Harrison Co., 12075 Greenfield St., Detroit 27, Mich.
Harrison, Ernest Burton ('45) (SFEKZC), Prod. Supt., St. Joseph Light & Power Co., 112 S. 2nd St., St. Joseph 5, Mo.
Harrison, Frank Hugh ('44), Ch. Mech. Engr., South Australian Ry. Comm., Islington Ry. Workshops, Lower North Rd., Islington; *for mail,* "Urrbrae," Esplanade, Tennyson, South Australia.

Harrison, Harry ('13; '19) (CK), Mech. Engr., East. Cold Storage Insulation Co., 101 Park Ave., New York 17; *for mail,* 55 Winthrop Ave., Tuckahoe 7, N.Y.
Harrison, J. Houston ('23), Mech. Engr., Valuation, So. Ry. System, Rm. 940, McPherson Sq., Washington, D.C.
Harrison, John Large (J'33) (CFEBAM), Engrg. Asst., Harrisburg Gas Co., 14 S. Market Sq., Harrisburg, Pa.
Harrison, Joseph Wiley (J'39) (CJKMYZ), Ch. Inspr., Norge Mch. Products Div., Borg-Warner Corp., 2969 Lake Shore Dr., Muskegon, Mich.
Harrison, Leroy Wallace ('45) (DJLMNO), Sales Engr., Faitoute Iron & Steel Co., Inc., 182 Frelinghuysen Ave., Newark 5; *for mail,* 216 Fabyan Pl., Newark 8, N.J.
Harrison, Maurice Robert (A'43) (CJMNLO), Secy., Treas., Dir., Behringer Metal Works, Inc., 108-22 Jabez St., Newark 5, N.J.
Harrison, Robert Edward William ('27) (JNMRHA), V.P., Chambersburg Engrg. Co., Derbyshire St., Chambersburg; *for mail,* Route 1, St. Thomas, Pa.
Harrison, Thomas J. (J'38) (CJM), Indus. Engr., Republic Steel Corp., Alabama City; *for mail,* 436—2nd St. E., Gadsden, Ala.
Harrod, Charles Franklin (J'41) (MCZAB), Asst. Engr., Crescent Tool Co., 200 Harrison St.; *for mail,* 351 Foote Ave., Jamestown, N.Y.
Harrod, Raymond Johnson (J'37) (RCS), Lt., U.S.N.R., Trans. Officer, Naval Mag., Bangor, Wash.; *for mail,* 2009 Ash St., Terre Haute, Ind.
Harshman, Donald Guy (J'45) (EKSHWZ), 2811 Ellis St., Bellingham, Wash.
Harszy, Charles H. (J'37) (SZ), Sr. Asst. Engr., Cahokia Power Plant, Union Elec. Power Co., Monsanto; *for mail,* 21 N. 41st St., Belleville, Ill.
Hart, David Anderson (J'43) (BKF), Design Engr., Westinghouse Elec. Corp., Lester; *for mail,* 913 Lincoln Ave., Prospect Park, Pa.
Hart, David K. (J'41) (EFKA), Apt. 107, 2517 Mozart Pl., N.W., Washington 9, D.C.
Hart, Frank Joseph (J'42) (AYC), Pvt., Co. F, 85th Mt. Inf., A.P.O. 345, c/o Postmaster, New York, N.Y.
Hart, Fred W. ('19), Pres., Brookridge Farm, Inc., Littleton, Colo.
Hart, Gordon Cole (J'43) (AMCSY), 40 Quincy St., Medford 55, Mass.
Hart, Herman A. (J'46) (BJL), Design Engr., Wyatt Metal & Boiler Works, Dallas 1; *for mail,* 2839 W. Clarendon, Dallas 11, Tex.
Hart, Howard P. ('15; '25), Asst. to Mgr., Platt Bros. & Co., Box 1030; *for mail,* 36 Buckingham St., Waterbury, Conn.
Hart, James Max (J'42) (ABMNWZ), Asst. to Sec., Schwarz Paper Co., 1430 S. Canal St., Chicago; *for mail,* 215 Orchard Lane, Highland Park, Ill.
Hart, John Seward ('45) (OCZF), Chicago Dist. Mgr., Cent. Sta. Steam Co., 80 E. Jackson Blvd., Chicago 4, Ill.
Hart, Lawrence Henry ('29; '35) (RBCDEM), Supvg. Engr., Tech. Trng., Dept. of Rys., 19 York St., Sydney, N.S.W., Australia.
Hart, Simeon Thompson ('24) (CGLMN), Head, Admin. Engrg., Syracuse Univ.; *for mail,* 168 Westminster Ave., Syracuse 10, N.Y.
Hartburg, Herman Louis ('23; '28) (CDKLOS), Dist. Supt., Great West. Sugar Co., Box 5308, Terminal Annex, Denver 17, Colo.
Hartenberg, Richard S. ('28; '40) (ABNWRH), Asst. Prof. Mechanics, Tech. Inst., Northwestern Univ.; *for mail,* 2448 Lincolnwood Dr., Evanston, Ill.
Harter, Isaac ('08; '21) (FSCMJL), V.P., Babcock & Wilcox Co., Barberton, Ohio.
Harter, Robert Jackson (J'42) (BANJ), Stress Analyst, Kellett Aircraft Corp., Baltimore Pike & Chester Rd., Swarthmore, Pa.
Hartford, Ernest (A'18) (CLW), *Executive Assistant Secretary,* A.S.M.E., 29 W. 39th St., New York 18, N.Y.
Harthorn, Paul Dudley (J'45) (LCFD), Graduate Work, Rensselaer Poly. Inst., Troy, N.Y.; *for mail,* West Pembroke, Me.
Hartin, Frank Robert (J'35) (SECBNJ), Lt., U.S.N., Naval Oper. Base, Guantanamo Bay, Cuba; *for mail,* 42 Jerome Ave., West Newton 65, Mass.
Hartley, Arthur Clifford ('45) (BPS), Ch. Tech. Dir., Petroleum Warfare Dept., Ministry of Fuel & Power; Ch. Engr., Anglo Iranian Oil Co., Ltd.; *for mail,* Britannic House, Finsbury Circus, London E.C. 2, England.
Hartley, Harry Dwight ('10; '21; '34) (CFKSW), 4051 Washington Blvd., Indianapolis, Ind.
Hartman, Elmer Charles ('34; '45) (ACEMNO), V.P., Engr., Technifinish Lab., Inc., 38 Scio St., Rochester 4, N.Y.
Hartman, Elmer Edward ('39) (BFS), 825 E. 21st, North Kansas City, Mo.
Hartman, Frederich Vincent ('31) (DEJKN), Mech. Engr., Tech. Div., Aluminum Ore Co., 3300 Missouri Ave., East St. Louis, Ill.
Hartman, James Busse ('42) (BEHSJK), Dept. of Mech. Engrg., Lehigh Univ., Bethlehem, Pa.
Hartman, John H. (J'37) (CRMAEY), 2336 Linn St., Williamsport 24, Pa.
Hartman, John M. ('20; '30) (FKS), Engr., Charge of Research Lab., Kewanee Boiler Corp., Kewanee, Ill.
Hartman, Joseph A. (J'40) (CMJ), Comdr., U.S.N.R., 8502—48th Ave., Berwyn, Md.
Hartman, Lawrence R. (J'36) (BKS), Consltd. Gas, Elec. Light & Power Co., Madison St. Bldg., Baltimore; *for mail,* 48 S. Dundalk Ave., Dundalk, Md.
Hartman, Wilmer W., Jr. (J'39) (OMCS), Staff Engr., Day & Zimmermann, Inc., Philadelphia, Pa.; *for mail,* 34 Overbrook Dr., Colwick, Merchantville, N.J.
Hartmann, Carl ('21; '35) (BCMNRZ), Designer, 3798 River Rd., Cincinnati 4, Ohio.
Hartmann, Melvin J. (J'44) ABHKNM), Mech. Engr., Natl. Advis. Com. for Aero., Cleveland Airport, Cleveland; *for mail,* 4562 W. 174th St., Cleveland 11, Ohio.
Hartmann, Warren J. (J'42) (HAB), Ch. Engr., Natl. Metal Products Corp., 21 N. Loomis St., Chicago 7; *for mail,* 3507 W. 26th St., Chicago 23, Ill.
Hartnell, George Freeman (J'39) (AZYMEB), 2nd Lt., Project Engr., Armament Lab., Engrg. Div., Matériel Comd., Wright Field, Dayton, Ohio.
Hartnett, Edward John (J'43) (MJB), Asst. Communications Officer, U.S.S. *Kitkun Bay,* CVE-71, Naval Sta., Tacoma 2, Wash.; *for mail,* 210 Charles Ave., Staten Island 2, N.Y.
Hartridge, Alfred Lamar ('41) (CO), Asst. Mgr., Stone & Webster Engrg. Corp., 90 Broad St., New York 4, N.Y.
Hartshorn, Derick Sibley ('40) (BCJM), Asst. Works Mgr., Cameron Mch. Co., 61 Poplar St., Brooklyn; *for mail,* 279 Washington Ave., Brooklyn 5, N.Y.
Hartsig, Albert L., Jr. (J'37) (CLS), Defender Div., E. I. du Pont de Nemours & Co., Box 1009, Rochester 3; *for mail,* 72 Vassar St., Rochester 7, N.Y.
Hartwell, Arthur Edward ('11; '13; '22) (CJM), Pres., Gen. Mgr., Hartwell Iron Works, Inc., 224 Rains St., Houston 2; *for mail,* Box 105, Houston 1, Tex.
Hartwell, Cushman ('45), Norris & Elliott Resident Engr. at Harwood Mfg. Corp., Inc.; *for mail,* Royal Oak Apts., Marion, Va.
Hartwell, George Warren (J'43) (NBKRAS), Design Engr., Worthington Pump & Mchy. Corp., Appleton, Holyoke; *for mail,* 55 Maple St., Springfield, Mass.
Hartwell, Hiram Britton ('03; '39) (MNZJBL), Mech. Engr., Crosby Steam Gage & Valve Co., 10 Roland St., Charlestown, Boston; *for mail,* 9 Townsend St., Waltham 54, Mass.
Hartwell, John Nathan (J'46), 111 Cherry St., Gardner, Mass.
Hartwell, Terence Canada (J'41) (AM), 1st Lt. (Pilot), Army Air Forces, 377th Sqd., 309th Bomb. Gp., Army Air Base, Columbia, S.C.; *for mail,* 5 E. Bissell Ave., Oil City, Pa.
Hartwell, Thurston ('45) (CLMKJN), Ch. Engr., Barnstead Still & Sterilizer Co., Inc., 2 Lanesville Terrace, Roslindale 31; *for mail,* 20 Pinewood Rd., Needham, Mass.
Hartz, Marvin Edward (J'42) (ABJ), Contract Engr., Goodyear Aircraft Corp., Akron; *for mail,* 160 Russell Ave., Akron 11, Ohio.
Harvey, Albert Henry ('32) (SCTNJK), Managing Dir., Inniss & Riddle (China) Ltd., 43 Yuen Ming Yuen Rd., Shanghai, Kiangsu, China.
Harvey, Alexander (J'46), Mech. Designer, Rapid Transit Dept., Toronto Trans. Comm.; *for mail,* 49 Foxbar Rd., Toronto, Ont., Can.
Harvey, Bruce Eugene (J'41) (AHB), Engr., Draftsman "A", Lockheed Aircraft Corp., 1705 Victory St., Burbank; *for mail,* 306 N. Electric St., Alhambra, Calif.
Harvey, Cyrus Robinson (J'32) (YAG), Estimator, Westinghouse Elec. Corp., Lester; *for mail,* 1 Drexel Rd., Swarthmore, Pa.
Harvey, Edmund Lukens (J'37) (A), Pvt., 1st Class, Army Air Forces, Sqd. A, Lowry Field, Denver, Colo.; *for mail,* Bancroft Rd., Moylan, Pa.
Harvey, James Edward (J'43) (BZM), 2895 Elmwood Ave., Ann Arbor, Mich.
Harvey, James Edward, Jr. (J'40) (CBMEGD), Lt. Comdr., Trng. in Industry (Pur.), Air Reduction Co., Inc., Rm. 1036, 60 E. 42nd St., New York, N.Y.
Harvey, James H. (J'45), 1931 S. Grove Ave., Berwyn, Ill.
Harvey, John C. ('42) (COMH), Ord. Engr., Boston Ord. Dist., 140 Federal St., Boston 10; *for mail,* 154 Beacon St., Chestnut Hill 67, Mass.
Harvey, Maurice Eugene (J'37) (NSBH), Design Engr., Westinghouse Elec. Corp., Lester; *for mail,* Ardmimink Arms, City Line & Childs Ave., Drexel Hill, Pa.
Harvey, Thomas Norman, Jr. (J'38) (BJE), Engr., Bob Hipp Welding Works, 1460 El Camino Real; *for mail,* 955 Fremont St., Menlo Park, Calif.
Harvill, Henry Lloyd ('44) (BJM), Pres., H. L. Harvill Mfg. Co., Box 335, Vernon 11; *for mail,* Box 301A, Route 3, Anaheim, Calif.
Harwick, Harry K. ('42) (RAFJB), Assoc. Engr., Edw. G. Budd Mfg. Co., 24th & Hunting Park Ave., Philadelphia 32, Pa.
Harwood, Harry P. (J'43) (YL), 103 E. Walnut St., Alexandria, Va.
Harz, Joseph, III (J'40), Lt. (j.g.); 1104 Crawford St., Vicksburg, Miss.
Harza, Leroy Francis ('19) (H), Pres., Harza Engrg. Co., 205 W. Wacker Dr., Chicago, Ill.
Hasegawa, Akira (J'41) (HJK), Engrg. Draftsman, County Regional Planning Comm., 205 S. Broadway, Los Angeles 12; *for mail,* 707 N. State St., Los Angeles 33, Calif.
Hasegawa, Tatsuo ('35; '45) (CHJKMY), Design Engr., Acting Ch. Draftsman, Dri-Steam Products, Inc., 559 W. 35th St., New York 1; *for mail,* 75 Wadsworth Terrace, New York 33, N.Y.
Haselberger, Ray E. (J'35) (AZY), Project Engr., Aero. Div., Minneapolis-Honeywell Regulator Co., 2753—4th Ave., Minneapolis; *for mail,* 408 N. Wheeler St., St. Paul 4, Minn.
Hashagen, John B. (J'20), 4236 N. Mozart St., Chicago, Ill.
Haskell, J. Dennis ('21; '31), Secy., Engr., Dilts Mch. Works, Inc., Fulton, N.Y.
Haskell, M. E. ('32), 3 St. James Court, Marine Dr., Bombay, India.
Haskin, Joseph Robert, Jr. ('42; '45) (CSEO), Steam Engr., Monsanto Chem. Co., 1700 S. 2nd St., St. Louis 4; *for mail,* 419 Clark Ave., Kirkwood 22, Mo.
Haskin, Lawrence Howard, Jr. (J'45) (ABCJM), Champlain Co., Inc., 88 Llewellyn Ave., Bloomfield, N.J.
Haskins, George William ('21; '26; '35) (ABCEF), Lt. Col., Army Air Forces, Commanding, Mills Field, San Bruno, Calif.; *for mail,* 283—28th Ave., San Francisco 21, Calif.

Heuser, Henry Vogt (J'36) (CMSF), V.P., Henry Vogt Mch. Co., Louisville 10, Ky.

Heverly, Earl L. ('37) (BCM), Gen. Mgr., Norton Door Closer Co., 2900 N. Western Ave., Chicago 18, Ill.

Hewey, Robert Warren (J'40) (BCMN), Mech. Engr., Singer Mfg. Co., 803 E. Washington Ave.; *for mail*, 195 Shelton St., Bridgeport 8, Conn.

Hewitt, Arthur R. (J'40) (CNMG), Ord. Engr., Frankford Arsenal, Bridge St. & State Rd., Philadelphia 37; *for mail*, 6203 Erdrick St., Philadelphia 35, Pa.

Hewitt, Edward R. ('18) (EFP), Cons. Engr., 48 Gramercy Park, New York 10, N.Y.

Hewitt, Ellis Eberle ('44) (NRAHMZ), Ch. Engr., Westinghouse Air Brake Co., Wilmerding, Pa.

Hewitt, Frederick McCracken ('45) (NCM), Dist. Engr., Bijur Lub. Corp., 4301—22nd St., Long Island City 1, N.Y.; *for mail*, 34016 Oakland Rd., Farmington, Mich.

Hewitt, George Edward (J'43) (CNYBJM), Design Engr., Radar Div., Gilfillan Bros., Inc., 1815 Venice Blvd., Los Angeles 6; *for mail*, 1011-B Western Ave., Glendale 1, Calif.

Hewitt, John Vance, Jr. (J'39) (CA), Lt. Comdr., U.S.N.R., U.S.S. *White Marsh*, F.P.O., New York; *for mail*, 970 Park Ave., New York 28, N.Y.

Hewitt, Reginald William (J'27) (CMDBJY), c/o Automatic Tel. & Elec. Co., Ltd., Liverpool 7, England.

Hewitt, William Barker ('20) (CMNY), Devel. Engr., North & Judd Mfg. Co.; *for mail*, 15 Emmons Pl., New Britain, Conn.

Hewitt, William Henry (J'37) (CJS), Direct Engrg. & Factory Rep. (Field), Jas. Morrison Brass Mfg. Co., Ltd., 276 King St. W., Toronto 2; *for mail*, 11 Abbott Ave., Islington, Ont., Can.

Hewlett, Allen Morton (J'41) (FGKLSZ), Factory Supt., Hutchinson Sugar Plantation Co. Ltd., Naalehu, Kau, Hawaii, T.H.

Heymann, Clifford Donald (J'41) (MNTCOA), Seaman, 2nd Class, U.S.N.R., Instr., Naval Acad. Prep. Sch. Crew, Naval Trng. Center, Bainbridge, Md.; *for mail*, 8802—104th St., Richmond Hill, L.I., N.Y.

Heyward, T. C., Jr. (J'39) (BCS), Dist. Engr., for T. C. Heyward, 1408 Independence Bldg., Charlotte 2; *for mail*, 1812 Winthrop Ave., Charlotte 3, N.C.

Heyward, Theo. C. ('15; '19) (FKS), Dist. Sales Mgr., Combustion Engrg. Co., Inc., 1408 Independence Bldg.; *for mail*, 2448 Mecklenburg Ave., Charlotte, N.C.

Heywood, Harold Lester ('41) (NJMHB), Supvr., Devel. Engrg., Kearney & Trecker Corp., 6784 W. National Ave., West Allis 14, Wis.

Hibbeler, Charles Leroy (J'41) (JMC), Plant Engr., John Nooter Boiler Works Co., 1400 S. 2nd St., St. Louis 4; *for mail*, 128 W. Etta, Lemay 23, Mo.

Hibbeler, Gletner Leonard (J'41) (LKDCZ), Design Engr., Monsanto Chem. Co., 1700 S. 2nd St., St. Louis; *for mail*, 5330 Pershing Ave., St. Louis 12, Mo.

Hickerson, Fred Rodrigo (J'43), Ridgewood Ave., Mt. Tabor, N.J.

Hickman, Charles Devitt ('14) (SFEO), Cons. Engr., Otis Bldg., Philadelphia 2; *for mail*, 2416 Bryn Mawr Ave., Philadelphia 31, Pa.

Hickman, Hally B. (J'34) (CEL), E. I. du Pont de Nemours & Co., Belle; *for mail*, 304 Main Dr., Charleston, W. Va.

Hickox, Charles M. ('40) (SFDKHZ), Mech. Engr., H. K. Ferguson Co., 1650 Hanna Bldg., Cleveland 15; *for mail*, 19627 Winslow Rd., Shaker Heights 22, Ohio.

Hickox, George Harold ('44) (HBSK), Sr. Hyd. Engr., Hyd. Lab., Tenn. Valley Authority, Norris, Tenn.

Hicks, Earl Junior (J'43) (ABHN), Stress Analyst, Structures Dept., Beech Aircraft Corp., Wichita 1; *for mail*, 341 N. Hillside Ave., Wichita 8, Kan.

Hicks, James Ryan ('32; '39) (ZSLH), Tech. Editor, Socony-Vacuum Oil Co., Inc., 26 Broadway, New York; *for mail*, 120 Gorey Brook Rd., North Tarrytown, N.Y.

Hicks, Melvin Leroy (J'45), Instr., Mech. Engrg. Lab., Univ. of Kan.; *for mail*, 1827 Massachusetts St., Lawrence, Kan.

Hicks, Robert William (J'42) (ABE), Ensign, U.S.N.R.; *for mail*, 1008 N. Walnut St., Brazil, Ind.

Hickson, William McLean ('45) (COS), Dist. Supt. of Erection, Babcock & Wilcox Co., 2511 Carew Tower, Cincinnati 2, Ohio.

Hider, George Turner ('11; '16; '35) (DES), Pres., Gen. Mgr., Hider Bros., Inc., Box 386, Lake Providence, La.

Hidley, Robert Wendell (J'42) (AMN), Mech. Engr., Design, Gen. Elec. Co., Schenectady; *for mail*, 227 S. Main Ave., Albany 3, N.Y.

Hiebeler, Harry G. ('19; '25; '35) (SECF), Asst. Supt., Power, Houston Ltg. & Power Co., Elec. Bldg., Houston; *for mail*, 5335 Blythewood, Houston 4, Tex.

Hiers, George O. ('28) (JNBOML), Metallurgist, Research Labs., Natl. Lead Co., 105 York St., Brooklyn 1, N.Y.

Hiersch, Frederick Alexander (A'43) (KBE), Sr. Project Engr., Al-Fin Corp., 184-10 Jamaica Ave., Jamaica 1; *for mail*, 112-07—177th St., St. Albans 12, L.I., N.Y.

Higbie, Vinton ('31; '35) (CARBJK), Pres., Gen. Mgr., Atlantic Casting & Engrg. Corp., 721 Bloomfield Ave., Clifton; *for mail*, 12 Llewellyn Rd., Montclair, N.J.

Higginbotham, Oscar ('26; '33) (AKS), Central Esparia, Perico, Cuba.

Higgins, Aldus Chapin ('16), Chmn., Exec. Com., Norton Co., 1 New Bond St., Worcester 6, Mass.

Higgins, Alexander ('36) (SEFMLN), Cons. Engr., 3620-8 A St. W., Calgary, Alta., Can.

Higgins, Bradley Carter (J'42) (CJMDBA), Asst. Plant Engr., Worcester Pressed Steel Co., 100 Barber Ave., Worcester; *for mail*, 12 Somerset St., Worcester 2, Mass.

Higgins, Charles Lewis (J'43) (NBZHMK), Lt., Design Sec., Supersonic Wind Tunnels Lab., Aberdeen Proving Ground, Md.; *for mail*, 4 Verdon St., North Plainfield, N.J.

Higgins, Edwin Melbourne (A'30) (NCLT), Ch. Engr., Master Lubricants Co., Meadow & Jackson Sts., Philadelphia, Pa.; *for mail*, 18 Hovey St., Watertown 72, Mass.

Higgins, John T. ('43) (SEFC), Asst. Ch. Engr., Prudential Ins. Co. of Am., 763 Broad St., Newark, N.J.

Higgins, John Woodman ('02; '13) (BCGJLM), Pres., Treas., Worcester Pressed Steel Co., 100 Barber Ave., Worcester 6, Mass.

Higgins, Nathan Bert ('26) (CHS), Pres., Safe Harbor Water Power Corp., Lexington Bldg.; *for mail*, Box 2097, Baltimore 3, Md.

Higgins, Roland Seymour ('44) (CZSFJK), 16620 Baylis, Detroit 21, Mich.

Higgins, Stephen Preston, Jr. (J'44), Mass. Inst. of Tech., Cambridge; *for mail*, 338 High St., West Medford 55, Mass.

Higgins, Theodore J., Sr. ('22; '27; '35) (CFS), Div. Engr., Consltd. Edison Co. of N.Y., Inc., 4 Irving Pl., New York, N.Y.; *for mail*, 184 Jefferson Ave., North Plainfield, N.J.

Higgins, Theodore John, Jr. (J'41) (SKFHCN), Jr. Engr., Consltd. Edison Co. of N.Y., Inc., 4 Irving Pl., New York, N.Y.; *for mail*, 184 Jefferson Ave., North Plainfield, N.J.

Higginson, Edmund Elder ('34) (FKLOST), Ch. Engr., Olson Rug & Carpet Mfrs., 2800 N. Crawford Ave., Chicago 41, Ill.

Higginson, Thomas H. ('21) (BCHO), Managing Dir., Automatic Sprinkler Co. of Can. Ltd., Jeanne Mance, Montreal, Que., Can.

Highum, Orvie (J'37) (CDNSEC), Mech. Engr., Riverside Cement Co., Riverside, Calif.

Higley, Frank Raymond ('18; '25; F'44) (E), Pat. Lawyer, 1020 Leader Bldg., Cleveland 14; *for mail*, 3009 Fairfax Rd., Cleveland Heights 18, Ohio.

Higman, James (J'38) (EMS), Mar. Engr., Mar. Dept., Union Oil Co. of Calif., Wilmington; *for mail*, 8736 Shoreham Dr., West Hollywood 46, Calif.

Hilands, William H. (J'36), Comdr., U.S.N., 4807—43rd Pl., N.W., Washington 16, D.C.

Hilbert, Wm. Michael ('31) (BDFJKS), Ch. Engr., U.S. Metals Refining Co., Carteret; *for mail*, 15 Munsee Dr., Cranford, N.J.

Hilbish, Frederick George (J'45) (CMNOYH), Ensign, U.S.N.R., Engrg. Officer, U.S.S. *Caperton*, DD-650, F.P.O., New York, N.Y.; *for mail*, Piney River, Va.

Hilborn, William Dwight (J'41) (SZL), Serv., Sales Engr., Bailey Meter Co., 1050 Ivanhoe Rd., Cleveland 10, Ohio; *for mail*, 8250 Park Place Blvd., Houston 12, Tex.

Hildebrand, H. Edw. ('20; '25; '35), V.P., Dir. of Engrg., Continental Baking Co., 630—5th Ave., New York, N.Y.

Hildenbrand, Charles Frederick (J'35) (SCMF), Engr., Power Prod., Consltd. Gas, Elec. Light & Power Co. of Baltimore, Lexington Bldg., Baltimore 3; *for mail*, 639 Regester Ave., Anneslie, Baltimore 12, Md.

Hilderbrand, Ewing Andrew (J'41) (EFJ), Field Engr., RCA Serv. Co., Inc., Radio Corp. of Am., Bldg. 5-6, Camden 2, N.J.

Hildestad, Harold Lyle (J'44), Devel. Engr., Aviation Gas Turbine Div., Westinghouse Elec. Corp., Lester; *for mail*, 313 Dartmouth Ave., Swarthmore, Pa.

Hildreth, William Osgood ('33; '30) (DABJMN), Engr., Lamson Corp., Lamson St., Syracuse 1; *for mail*, 122 Rigi Ave., Syracuse 6, N.Y.

Hilera, Pedro (J'45) (CMS), Engr., P.R. Pulp & Paper Corp., P.O. Box 2072, San Juan, P.R.

Hiles, Elmer K. ('00; '06), Gulf Oil Corp., 458 Gulf Bldg., Pittsburgh, Pa.
Hilgartner, George Henry ('13) (BFHRS), Retired; 3013 Brook Rd., Richmond 22, Va.
Hilgert, Adolph John (J'42) (BKSZ), Design Engr., Johnson Serv. Co., 507 E. Michigan St., Milwaukee 2; *for mail,* 1720-A W. Meinecke Ave., Milwaukee 6, Wis.
Hilke, John Lewis (J'43), Student Test Engr., Gen. Elec. Co., Schenectady; *for mail,* 140 Otsego St., Canajoharie, N.Y.
Hilker, Harold William (J'42) (BCMNSZ), Mech. Engr., Bailey Meter Co., 1050 Ivanhoe Rd., Cleveland 10; *for mail,* 1832 Willowhurst Rd., Cleveland 12, Ohio.
Hill, Albert J. ('32; '41) (CMS), Ch. Engr., Haytian Am. Sugar Co., Port-au-Prince, Haiti, W.I.
Hill, Arthur Lefevre ('24; '37) (MZTCFY), V.P., Natl. Fuse & Powder Co., 3801 Delgany St., Denver 5; *for mail,* 1033 Humboldt St., Denver 3, Colo.
Hill, Arthur Middleton ('39) (SEK), Prof. Heat Engrg., Tulane Univ., New Orleans 15, La.
Hill, Charles F. (J'41) (CJM), Lt. (j.g.), U.S.N.R., 10646 Ave. F, Chicago, Ill.
Hill, Chas. H. (A'07) (B), Retired; 628 Foss Ave., Drexel Hill, Pa.
Hill, Charles St. John (J'39) (ASR), Sr. Test Engr., Wright Aero. Corp., Beckwith Ave., Paterson 3; *for mail,* 152 Valley View Ave., Ridgewood, N.J.
Hill, Charles Strunk, Jr. ('45) (MDJOWZ), Cons. Engr., 301 S. 15th St., Philadelphia 2, Pa.
Hill, E. Rowland ('07) (ERS), V.P., Gibbs & Hill, Inc., Pa. Sta., New York 1, N.Y.
Hill, Ebenezer ('00; '07), c/o A.S.M.E., 29 W. 39th St., New York, N.Y.
Hill, Edgar Goodspeed ('21) (CEO), V.P., Ford, Bacon & Davis, Inc., 39 Broadway, New York 6, N.Y.
Hill, Erland Victor (J'45) (ESJWRN), Co-Partner, Foreman, Hill Timber Co., Battle Ground, Wash.
Hill, Erle Gladstone ('45) (JCFK), Dir. of Metal. & Devel., Wheeling Steel Corp., Wheeling Steel Bldg., Wheeling, W. Va.
Hill, Frank (J'32) (FKOST), Co-Partner, Firm of Geo. Hill, Engr., Box B, Wellford; *for mail,* Duncan, S.C.
Hill, Fred Carlton ('21; '35) (CFER), Supt., Coke Plant, N.Y. Power & Light Corp., Troy, N.Y.
Hill, Fred M. ('38) (BCMNS), Serv. Mgr., Manning, Maxwell & Moore, Inc., 11 Elias St., Bridgeport; *for mail,* 203 Edison Rd., Bridgeport 14, Conn.
Hill, G. A. ('40), Supt. M.P. & Cars, Wheeling & Lake Erie Ry. Co., Brewster, Ohio.
Hill, George Blood (J'36) (CMBJ), Designing Engr., Dain Mfg. Co., Vine St.; *for mail,* 238 S. Adella St., Ottumwa, Iowa.
Hill, George Mitchell ('44) (CMSRHY), Supvr., Civ. Sec., Pub. Works Design, Naval Shipyard, Terminal Island; *for mail,* 238 Coronado Ave., Long Beach 3, Calif.

Kramer, Delbert F. (J'36), 16881 Pierson Ave., Detroit 19, Mich.
Kramer, Frank Kipp, Jr. (J'41) (FSW), 714 W. Main St., Elizabeth City, N.C.
Kramer, Harold K. ('24; A'39) (C), Asst. V.P., Borden Co., 350 Madison Ave., New York 17; *for mail,* 27 Willets Court, Plandome, N.Y.
Kramer, Karl S. ('39) (SNJB), Asst. Sec. Engr., Westinghouse Elec. Corp., Lester Branch P.O., Philadelphia 13; *for mail,* 624 Delaware Ave., Norwood, Pa.
Kramer, Leo Judson ('38; '45) (MLCNYD), Engr., Product Devel., Raytheon Mfg. Co., 1065 Commonwealth Ave., Boston; *for mail,* 31 Auburn St., Brookline 36, Mass.
Kramer, Stanley Frederick (J'43) (ECM), Ensign, U.S.N., c/o Indus. Mgr., 8th Naval Dist., 1 Canal St.; *for mail,* 5347 Coliseum, New Orleans, La.
Kramer, Vincent Joseph (J'41) (MCA), Asst. Ch. Engr., Smith & Mills Co., 2889 Spring Grove Ave., Cincinnati 25; *for mail,* 4113 Smith Rd., Norwood 12, Ohio.
Kramer, Wilbur C. ('37) (SFKH), Effic. Supt., Chicago Dist. Elec. Generating Corp., Box 65, Hammond, Ind.; *for mail,* 10622 Ave. E, Chicago 17, Ill.
Kramer, William Henry, Jr. ('44) (EFSKLC), Sales Engr., Phillips Petroleum Co., 80 Broadway, New York 5, N.Y.; *for mail,* 362 Thomas St., Phillipsburg, N. J.
Kramlich, C. W. ('29), 828 N. Broadway, Milwaukee, Wis.
Kranich, Henry Oscar ('36) (BMN), Engr., Libbey-Owens-Ford Glass Co., E. Broadway, Toledo; *for mail,* 2454 Hempstead Rd., Toledo 6, Ohio.
Krannert, Herman C. ('17; '35) (CDW), Pres., Inland Container Corp., Indianapolis, Ind.
Krantz, Clayton John (J'43), 3018 Logan Ave. N., Minneapolis 11, Minn.
Krantz, LeRoy J. (J'40) (ABK), Estimating Engr., Burge Ice Mch. Co., 218-20 N. Jefferson St., Chicago; *for mail,* 122 S. Cuyler Ave., Oak Park, Ill.

Krase, John Miles (J'44) (KNBCAF), 1234 Mt. Vernon Ave., Dayton 5, Ohio.
Krasner, Morton Harold (J'44), 16 Boston St., Malden, Mass.
Kratz, Alonzo Plumsted ('13; '21) (EFK), Research Prof., Dept. of Mech. Engrg., Univ. of Ill., Urbana, Ill.
Kratzer, James Carl (J'35) (FEABK), Div. Head, Research Lab., Linde Air Products Co., E. Park Dr., Tonowanda; *for mail,* 394 Washington Ave., Kenmore 17, N.Y.
Kraus, Benjamin Franklin ('44) (CSRTHA), Dir. of Inspc., Inspc. Dept., Assoc. Factory Mutual Fire Ins. Cos., 184 High St., Boston 10; *for mail,* 246 Fairmount Ave., Hyde Park 36, Mass.
Kraus, Charles Edward ('33; '35; '35) (JMC), Owner, Kraus Engrg. Co., 228 Winton Rd. N.; *for mail,* 100 Edgemoor Rd., Rochester 10, N.Y.
Kraus, Charles Elmer ('23) (CHM), Engr., Springfield Mch. Tool Co., W. Southern Ave.; *for mail,* R.D. 1, S. Tecumseh Rd., Springfield, Ohio.
Kraus, Gerard (J'43) (YJZ), Research Fellow, Applied Sci. Research Lab., Univ. of Cincinnati, Cincinnati 21, Ohio.
Kraus, Milton Nathaniel ('36; '45) (BES), Asst. Plant Engr., City Plants, Sheffield Farms Co., Inc., 524 W. 57th St., New York; *for mail,* 74 Clinton Pl., New York 53, N.Y.
Kraus, William Robinson (J'38) (MCDN), V.P., Prod. Mgr., Plant 2, Wm. Powell Co., 3233 Colerain Ave., Cincinnati; *for mail,* 1204 N. Bend Rd., Cincinnati 24, Ohio.
Krause, James Lawrence (J'42) (NMSDJC), Mech. Engr., T. C. Wheaton Co., 3rd & G St.; *for mail,* 518 E. Main St., Millville, N.J.
Krause, Otto C., Jr. (J'37) (SZFKBH), Economy Engr., Canal Sta., Louisville Gas & Elec. Co., 2005 Northwestern Pkwy., Louisville 3, Ky.
Krause, Robert ('36; '41) (LCMSDO), Asst. Plant Mgr., Container Corp. of Am., 404 E. N. Water St., Chicago 11; *for mail,* 17827 Tipton St., Homewood, Ill.
Krause, Robert Martin ('30; '35) (AECMJN), Prod. Engr., Gen. Elec. Co., 920 Western Ave.; *for mail,* 38 Manning Rd., Lynn, Mass.
Krauss, Arthur H. ('20; '23; '35) (SFE), Mech. Engr., Ebasco Services, Inc., 2 Rector St., New York 6, N.Y.; *for mail,* 254 Lenox Ave., South Orange, N.J.
Krauss, Harry Edward, Jr. ('45) (OCMJN), Ch. Engr., Dennis Mitchell Industries, 4424 Paul St., Philadelphia; *for mail,* 7417 Miller Ave., Upper Darby, Pa.
Kraut, Hans B. ('16) (CHN), Chmn., Bd. of Dirs., Giddings & Lewis Mch. Tool Co.; *for mail,* 15 S. Park Ave., Fond du Lac, Wis.
Krauth, Joseph Anthony, Jr. (J'42) (SKHR), 8504—123rd St., Richmond Hill 18, N.Y.
Krautheim, Wm. Chas. ('42) (RBJ), Asst. Mech. Engr., Gen. Steel Castings Corp., Granite City, Ill.; *for mail,* 7522 Forest View, St. Louis, Mo.
Kreamer, William Howden (J'37) (NTKLMB), Staff Engr., Am. Viscose Corp.; *for mail,* R.D. 6, Meadville, Pa.
Krebs, Edward P. (J'40) (BJM), 1726 Hollywood St., N.E., Warren, Ohio.
Krebs, Frank J. (J'28) (CMY), Engr., U.S. Rubber Co., 1230—6th Ave., New York 20, N.Y.; *for mail,* 603 Sunderland Rd., West Englewood, N.J.
Krehbiel, Fred. A. ('02; '30) (DEKMNS), Owner, Fred. A. Krehbiel Engrs., Rm. 1454, 222 W. Adams St., Chicago 6, Ill.
Krehbiel, Homer C., Jr. (J'37), Looper, Bethlehem Steel Co., W. Andover & 28th Ave., S.W., Seattle; *for mail,* 4600 W. Lander St., Seattle 6, Wash.
Kreiberg, Theodore N. (J'38) (OCYGNJ), Elec. Engr., U.S. Bur. of Reclamation, Redding, Calif.
Kreidler, D. W. ('17), Engrg. Staff, Hudson Motor Car Co., Detroit; *for mail,* 633 Lincoln Rd., Grosse Pointe, Mich.
Kreiner, Anthony James (J'42) (AHBE), Asst. Gen. Mgr., Designers for Industry Inc., 2915 Detroit Ave., Cleveland 13; *for mail,* 399 Lloyd Rd., Wickliffe, Ohio.
Kreisinger, Robert H. (J'38) (BFS), Gilbert Associates, Inc., 412 Washington St., Reading; *for mail,* 19 Woodland Rd., Wyomissing, Pa.
Kreith, Frank (J'46), Research Engr., Inst. of Tech.; *for mail,* 722 N. Westbourne, Los Angeles 46, Calif.
Kreitler, Frank C., Jr. (J'38) (MJNCRB), Requisition Engr., Trans. Motor Eng. Div., Gen. Elec. Co., 2901 E. Lake Rd., Erie; *for mail,* 317 E. Main St., Girard, Pa.
Krejci, Emil Louis (J'26) (CRDM), Works Mgr., Am. Steel Fdys., 4831 Hohman Ave., Hammond, Ind.; *for mail,* 2548 Indiana Ave., Lansing, Ill.
Kremer, Waldemar R. ('12) (CEFSYZ), 3348 N. Lake Dr., Milwaukee 11, Wis.
Kremser, Alois ('43) (FEACSY), Tech. Adviser to Pres., Stand. Oil Co. of Calif., 225 Bush St., San Francisco; *for mail,* Box 66, Alamo, Calif.
Kresser, Leo ('22) (BA), 114 Albermarle St., Springfield 9, Mass.
Kretzmer, Minor Garfield, Jr. (J'44) (BCZNKD), Research & Devel. Engr., Hartford-Empire Co., Homestead Ave., Hartford, Conn.
Kreuter, Verner Conrad (J'38) (CDJMNS), Engr., Am. Laundry Mchy. Co., 110 Buffalo Rd., Rochester 11, N.Y.
Krewson, William Lowley (J'44), 93 S. Rolling Rd., Springfield, Pa.
Krider, Harry Read (J'33) (CMS), 941 Rosewood Dr., Grand Rapids 6, Mich.
Krieg, Edwin Holmes ('25; '33) (SFKEBL), Cons. Mech. Engr., Am. Gas & Elec. Serv. Corp., 30 Church St., New York 8, N.Y.; *for mail,* 40 Sherwood Rd., Ridgewood, N.J.
Krieg, J. L. ('43) (JK), 9321—202nd St., Hollis, N.Y.
Kriegsheim, Heinrich ('24) (SBJZ), Retired; 200 W. 86th St., New York 24, N.Y.
Kriek, Peter Paul ('30) (TSL), Ch. Engr., Am. Enka Corp., Enka, N.C.
Kriger, Ralph Stacy ('44) (NHMBD), Engr., Mech. Research Dept., Corning Glass Works; *for mail,* 82 E. 3rd St., Corning, N.Y.
Krinner, Ludwig (J'44) (BEJKLS), Mech. Designer, Foster Wheeler Corp., 6 Church St.; *for mail,* 155 W. 76th St., New York, N.Y.
Krishnamurthy, B. S. ('28; '35), Gen. Mgr., Mysore Implements Factory, Hassan, Mysore State, South India.
Kristl, Franklin R. (J'46), 1116 E. 3rd Ave., Mishawaka, Ind.
Kriva, John Anton (J'43) (CODNMJ), Plant Layout Engr., J. I. Case Co., 700 State St.; *for mail,* 2316 Ashland Ave., Racine 2, Wis.
Kroder, Ernest Andrew (J'45) (DCFHZB), Plant Layout Engr., Bridgeport Brass Co., 30 Grand St., Bridgeport 2; *for mail,* 18 Hadley St., Bridgeport 8, Conn.
Kroeger, Edwin John (J'37) (ACKFYJ), Branch Head, Air, Sea Rescue & Safety Equip., Engrg. Div., 2W40 Navy Dept., Washington 25, D.C.
Krohn, Philip (J'43) (MCS), 2766 Barnes Ave., Bronx 67, N.Y.
Krol, Peter Frank ('43) (EJKHCF), Engr., Tide Water Associated Oil Co., E. 22nd St., Bayonne; *for mail,* 16 Doering Way, Cranford, N.J.
Kroll, Joseph (J'41) (ACM), Lt., Box 224, Advanced Cadet Det., Selman Field, Monroe, La.
Kroll, Leonard Arthur (J'35) (NJRM), Mch. Shop Instr., Gompers Vocational High Sch., 455 South Blvd., Bronx 55; *for mail,* 944 E. 13th St., Brooklyn 30, N.Y.
Kromer, William F. ('24) (RELOB), Ch. Mech. Engr., Charge of Sales & Engrg., H. K. Porter Co., Inc., 49th & Harrison Sts., Pittsburgh 6, Pa.
Kroner, Ernst Frederic ('28; '35) (AEH), Gen. Delivery, Fryeburg, Me.
Kroon, R. P. ('32; '41) (ABH), Mgr., Devel. Div., Westinghouse Elec. Corp., Lester Branch P.O., Philadelphia; *for mail,* Box 308, 1141 Muhlenberg Ave., Swarthmore, Pa.
Krooss, John H. (J'25) (YHJB), Ch. Engr., Victaulic Co. of Am., 30 Rockefeller Plaza, New York 20, N.Y.
